Monthly mean mineral aerosol concentrations at Guiana (Fig. 1) were determined from daily filter samples collected at a coastal site by weighing the residue after extracting the filter with water and ashing at 500 °C (ref. 9). The greatest mineral aerosol concentrations are observed early in the year with the maximum monthly mean occurring in March in both 1978 and 1979. The Cayenne annual maximum values (29 $\mu g\ m^{-3}$ and 23 $\mu g\ m^{-3}$ for 1978 and 1979 respectively) are markedly higher than the annual maximum monthly means for Barbados which were in the range 15–18 $\mu g\ m^{-3}$ between 1976 and 1979; the annual maximum at Barbados occurred during June, July or August.

The day-to-day variability of the mineral dust concentration in Cayenne is quite large. This can be seen in Fig. 2 which presents data for March 1978. Similarly large variations have been measured at other stations in the tropical North Atlantic during the summer[9,10,15,16].

We analysed the mineralogical composition of 29 aerosol samples by X-ray diffraction[11]. The samples were selected to represent the periods of highest dust concentration each month. The samples can be divided into three mineral groups. One group of 13 samples has the same composition as the dust from North Africa previously collected from ships and island stations in the tropical North Atlantic[11]. The second group of 12 samples has a distinctly different composition from that of African dust and which we attribute to the presence of soil material derived from the land mass of South America, most likely Brazil. The mean composition of these two groups is presented in Table 1*a*. The third group of four samples has a composition that suggests that the samples are a mixture of typical North African and South American soil material.

Using satellite imagery we focused on the two dust concentration maxima occurring on 21–22 and 24–25 March (Fig. 2). A search of GOES satellite imagery at the National Environmental Satellite Service yielded a sequence of photographs showing two dust outbreaks emerging from the coast of Africa, a relatively weak one on 16–17 March and a major one on 20–22 March; the dust clouds could be followed across the Atlantic in the photographic sequence. The transit time across the Atlantic is 4–5 days, and the distance covered ~4,000 km.

The passage of the dust clouds was detected at several stations in an aerosol network established in the tropical North Atlantic since 1974. At Dakar, Senegal (14°44'N, 17°33'W), the dust concentration reached a maximum of 580 $\mu g\ m^{-3}$ on 21 March, the day on which the satellite photographs show the main plume emerging from the coast. The outbreak of 17 March yielded a dust load of 270 $\mu g\ m^{-3}$ at Dakar.

Our long-term studies at Barbados indicate that very high concentrations would not be expected at this time of year. In fact, the first of the two dust outbreaks passed to the south of the island, and there was no large increase in dust load on 21 and 22 March. However, on 25 and 26 March the dust load increased dramatically from 6 to 104 $\mu g\ m^{-3}$; on 27 March it dropped to 5 $\mu g\ m^{-3}$. Focusing on the second and largest outbreak, we selected from each station the filter collected during the peak dust concentration period and analysed it by X-ray diffraction (Table 1*b*). Clearly, the dust mineralogy at Cayenne is essentially the same as that of the samples from the other stations. The similarities both in the mineralogies of the Cayenne and Barbados dust samples in this one dust episode, and between this one Cayenne sample and the bulk of those collected during the winter and spring in Cayenne suggest that these aerosols are indeed of African origin.

The wind climatology of French Guiana is consistent with the observation of Saharan dust in winter and Brazilian and local dusts in summer. The large-scale circulation is principally determined by the position of the equatorial trough (that is, a latitudinal belt of relatively low pressure) commonly referred to as the intertropical convergence zone (ITCZ) which can be pictured as the area of convergence between the north-east and south-east trade wind regimes[17]. The ITCZ translates meridionally on a seasonal basis about its annual mean position at 5°N. In the winter months, when the ITCZ is in its most southerly position, Cayenne lies on the northern edge of the ITCZ causing the winds at Cayenne to be predominantly north-east (57%) and east (32%); they are also relatively steady with only a 0.4% incidence of calms[18]. In the summer, the ITCZ is in its most northerly position and Cayenne lies well within the ITCZ circulation; although winds are predominantly north-east

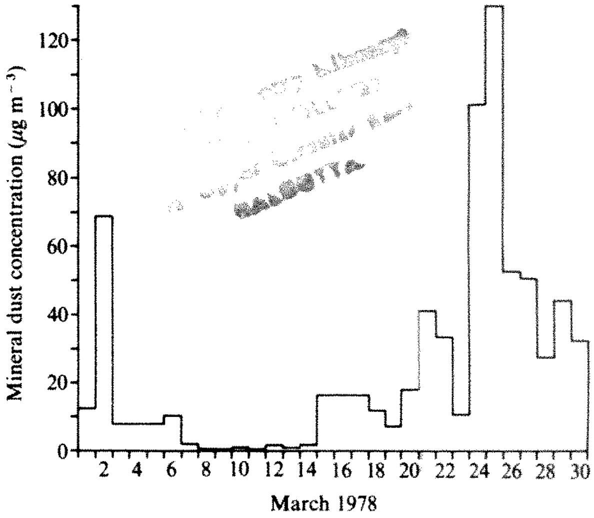

Fig. 2 Daily mineral dust concentration in surface level air at Cayenne, French Guiana, during March, 1978. The periods of relatively high dust concentration are all attributable to incursions of air parcels containing dust advected from North Africa.

(24%), east (41%) and south-east (18%), they are not so steady in speed or direction and there are significantly more periods of light and variable winds or of calm[18]. Saharan dust is occasionally transported into the Cayenne region during the summer on north-east winds, but the concentrations are never as great as during the winter. Of our 29 analysed samples, three of the four samples of mixed African and South American mineralogies were collected during the summer months.

The mineralogy of the aerosol samples placed in the South American group in Table 1*a* is consistent with the known characteristics of the soils in this region. The soils of French Guiana and much of the north-east are predominantly laterites formed by the intensive chemical weathering processes that are common to hot, humid, tropical climates. Such highly leached soils are typically characterized by the presence of high concentrations of iron-oxide minerals (geothite, haematite) and aluminum oxide minerals (gibbsite, boehmite), the relative amounts of which are determined by the chemical and mineral composition of the underlying bedrock. Indeed, the concentration of aluminum oxide minerals is often so great that gibbsitic bauxites are mined in French Guiana, Venezuela, Brazil and Surinam.

Much of the summer and autumn dust collected at Cayenne is relatively fine grained which suggests that it has been transported over a considerable distance. Given the dominance of the south-east trade winds in these seasons, this soil material is most likely derived from the eastern portions of Brazil. In the summer and autumn, the aerosol filters are often blackened by a component that seems to be elemental carbon from combustion sources. This material could come from local anthropogenic sources such as cars in the Cayenne area during periods of south and south-west winds; however, the population of Cayenne is rather small (the entire population of French Guiana was only 55,000 in 1975). We suspect that the black material might be a product of cut-and-burn agriculture which is common in the northeastern portion of South America, especially Brazil. Burning is most intensive in the dry season (late summer to autumn). The summer–autumn samples also often contain much organic material, especially plant fibre and insects. In contrast, the winter (African) dust is always very fine textured, has a beige colour characteristic of Saharan aerosols, and is essentially devoid of readily identifiable biological material.

Previous studies suggest that the African dust collected during the peak concentration period comes from the western and central Sahara and bordering regions to the south[19–25]. Although we have not attempted a detailed study of possible sources for the winter dust, the GOES satellite imagery for March 1978 suggests that these same areas might be active in the winter. There is also considerable dust storm activity in Chad and Niger during December to February[19–21,24,25]; as a consequence of these storms, extremely dusty air masses, known as the harmattan, penetrate to the Gulf of Guinea. The coincidence of maximum dust activity along the coast of the Gulf with the time of minimum dust transport to the region of French Guiana suggests that this massive transport of dust must be terminated by fairly complete removal, probably in the regions of high precipitation that are characteristic of the ITCZ.

The transport of dust out of Africa into and across the Atlantic has important implications. First, the quantity of dust being transported has been estimated to be in the range of 100–400 megatons (where 1 megaton = 10^{12} g) per yr (refs 13, 15, 26). Our results support the upper range of estimates. Such quantities of material could provide a very substantial fraction of the non-biogenic material entering the deep-sea sediments in the tropical and equatorial North Atlantic[12,15]. Second, 8.5% of the dust mass collected over the western Atlantic consists of particles (density, 2.5 g cm^{-3}) with diameters greater than 12 μm (ref. 27); the equivalent aerodynamic diameter of particles having a density of 1 g cm^{-3} would be 20 μm. Therefore many types of fungal spores (which usually have diameters between 5–20 μm) could be transported across the Atlantic in a viable state; such a transport might be of aerobiological significance. Finally, concentrations[26] of Saharan dust comparable with those measured in French Guiana can produce a marked increase in heating rates in the middle troposphere and a cooling at the surface[28]. This increases atmospheric stability to the extent that there may be a significant impact on the meteorological processes occurring over a large area of the topical and equatorial North Atlantic.

We thank R. Causse and C. Dardeau for supervising the sampling programme in Cayenne and D. Moreau and J. Rine for technical assistance. This work was supported by the Division of Atmospheric Sciences, NSF grants ATM76-02198 and ATM78-12246.

Coloured materials and photoluminescence centres in anodic film on aluminium

Y. Yamamoto, N. Baba & S. Tajima

Laboratory of Electrochemistry and Inorganic Chemistry,
Tokyo City University, Tokyo 158, Japan

Anodic oxide films formed on aluminium in lower aliphatic carboxylic acids exhibit self-colouring of yellow through brown, and characteristic properties such as photoluminescence (PL), electroluminescence (EL), and electron spin resonance (ESR). These phenomena are closely associated with the carboxylate species incorporated in the oxide during anodization[1]. Although the presence of incorporated carboxylate species in some cases[2,3] and their distribution in oxalic acid film have been established[4], there have been little data available on the state of incorporated impurities in the oxide. We have studied the distributions of coloured material and PL centres in the oxide and report here that most of the coloured material is located in the outer region of the cell walls of an oxalic acid film, but that the PL centres are in the middle region and have different properties from those of the outer region. These results suggest that the incorporated impurities which are present in the various states in oxide have to be converted during anodization.

0028–0836/81/070572–03$01.00

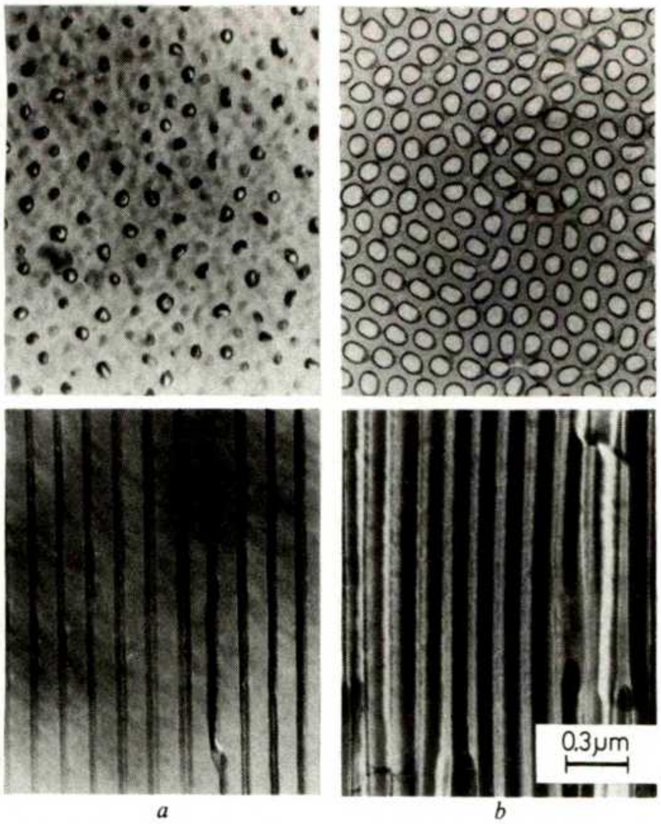

Fig. 1 Replica electron micrographs, showing the increase of pore diameters of the porous film with elapse of open-circuit dissolution time: *a*, as-anodized film formed on electropolished 99.99% aluminium at 3.0×10^{-2} A cm^{-2} in 0.5 M oxalic acid at 303 K for 60 min; *b*, the film dissolved for 140 min in 1M sulphuric acid at 313 K. Upper micrographs are the top surfaces and lower micrographs are the fractured sections of each film, respectively.

Figure 1 shows the open-circuit dissolution of the oxalic acid film in 1M sulphuric acid. The electron micrographs show that the pore widening occurs uniformly throughout the film[5]. Thus, it seems possible to determine the distribution of incorporated impurities across the pore walls by varying the dissolution period.

Figure 2 shows the variation of colour intensity of the film in terms of the integration of absorbance in the visible range (400–700 nm) by curve *A*, and PL intensity of the film with 310 nm excitation by curve *B* against the dissolution time T_d or the distance X from the surface of the pore wall. Curve *A* shows that the film decolours gradually in the first 90 min (0–225 Å), and then more rapidly during the next 90 min (225–450 Å). The yellow colour of the film disappears near this point and the film becomes semi-transparent. The distribution of the coloured materials calculated from curve *A* by differentiation with the amount of the dissolved oxide measured by gravimetry is shown in Fig. 3 *A*. The coloured material is located predominantly in the outer region of the cell walls (a, 0–225 Å); decreasing steeply in the next middle region (b, 225–450 Å) and none in the inner region (c, 450–540) Å). The distribution is shown in Fig. 3*B* together with the cell dimensions measured from the micrographs. This profile indicates that the hypothesis[6,7] of a uniform distribution of coloured materials in self-colouring films is no longer valid. In addition, this profile is in general agreement with that reported[4] for oxalate ions in the film calculated from the carbon content.

Curve *B* in Fig. 2 reveals that the PL centres are located predominantly in the middle region (b) of the pore walls. Note that the films dissolved for up to 90 min show relatively lower PL intensity, though the middle region still existed. This indicates that the outer coloured region (a) of the film tends to disturb the transmittance of excitation light, and emission light from the middle region (b).

Figure 4 shows the variation of the emission spectra with dissolution time when the film is excited by 310 nm light. The emission peak of the film shifts towards the shorter wavelength (470–435 nm) after a period of dissolution. Such a change became pronounced near the point ($T_d = 90$ min, $x = 225$ Å) when the outer coloured region (a) was dissolved. Furthermore, greenish-yellow phosphorescence with a peak at 560 nm with 360 nm excitation was observed in the coloured film containing region (a), but not in the inner film containing only region (b) and/or region (c). Therefore, luminescent centres in the outer region (a) and the inner regions (b, c) are clearly different.

In accounting for the appearance of these phenomena, there must be some conversion of aluminium–oxalate complex incorporated in Al_2O_3 matrix because the stoichiometric trioxalatoaluminate complex shows neither a yellow colour nor PL or ESR. A definite mechanism of the postulated conversion process has not yet been clarified; however, recent work[8] has produced a plausible model for the mechanism of successive transformation of aluminium–carboxylate complex into PL centres and coloured materials. According to this model, the carboxylate ions incorporated in the barrier oxide layer are subjected to decomposition followed by eventual polymerization. These processes are supposed to be induced by the collision of energetic (~2–5 eV, from EL spectra) electrons[9] that are injected into the conduction band of the oxide from the electrolyte at the oxide–electrolyte interface and have acquired such high kinetic energy due to the high electric field near 10^7 V cm^{-1} set up inside the oxide, or to be induced by Joule's heat. Thus, the carboxylate ions are expected to transform into intermediate compounds (luminescent centres) and finally, into coloured materials—mostly tarry products dispersed. This

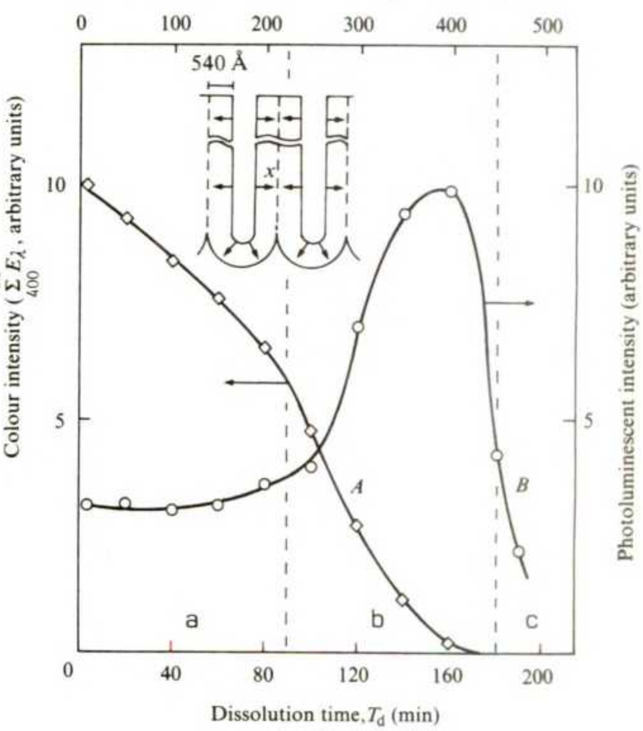

Fig. 2 Variations of the colour intensity of the film in terms of the integration of absorbance in the visible range (400–700 nm) (*A*) and PL intensity of the film with 310 nm excitation (*B*) against the time (T_d) of open-circuit dissolution or the distance (x) from the surface of the pore wall determined from mean dissolution rate of the film. The films were formed anodically on electropolished 99.99% aluminium at 3.0×10^{-2} A cm^{-2} in 0.5 M oxalic acid at 303 K for 60 min. After isolating the films from the metals, they were dissolved in 1 M sulphuric acid on open-circuit at 313 K for various times.

model is verified[10] by the thermosynthetic simulation of the anodic colouring process where the self-coloured alumina prepared by baking a mixture of hydrated $Al(OH)_3$ gel and carboxylic acid (molecular ratio 2 : 3) showed almost the same colour, PL and ESR characteristics as those of the anodically coloured alumina.

One possible explanation for the observed distributions of coloured materials and PL centres is given by the non-linear gradient of electric field across the barrier layer. The field strength, *F*, should increase between the cell base (wx) and the pore base (yz) (Fig. 3 *B*), as suggested by Hoar and Mott[11]. We can estimate the field strength in the oxide using the values given by Harkness and Young[12],

$$j = j_0 \exp -(w - qaF)/kT$$

where, $j_0 = 2.24 \times 10^7$ A cm^{-2}, $w = 1.3$ eV, $q = 3\,e$, $a = 2.95$ Å. In the present case, the field *F*, at the cell base corresponding to a current density of 3.0×10^{-2} A cm^{-2} at 303 K is then 8.96×10^6 V cm^{-1}. At the pore base, *F*, corresponding to a current density of about 3×10^{-1} A cm^{-2} at 303 K is then 9.60×10^6 V cm^{-1} because the pore base area is about one-tenth of cell base area. Thus, the field of outer region of the barrier layer is larger by ~7% than the inner region. In the outer region (a) of the barrier layer where the electric field is higher, the incorporations of oxalate ions and their conversions into PL centres or coloured materials should become more pronounced due to the high electric field. At steady state during anodization, the field-assisted dissolution[11,13] is balanced by the oxide growth at the cell base causing the continuous process of the anion incorporation and their conversion, and the transformation of the barrier layer to the cell wall of the porous layer. This would explain the development of distributions of the coloured materials and PL centres in the cell walls. However, the role of incorporated impurities on electric field cannot be neglected: an increase in the field has been shown by Dell'Oca and Young[14] whereas a decrease has been suggested by Thompson *et al.*[15]—this problem is still under discussion.

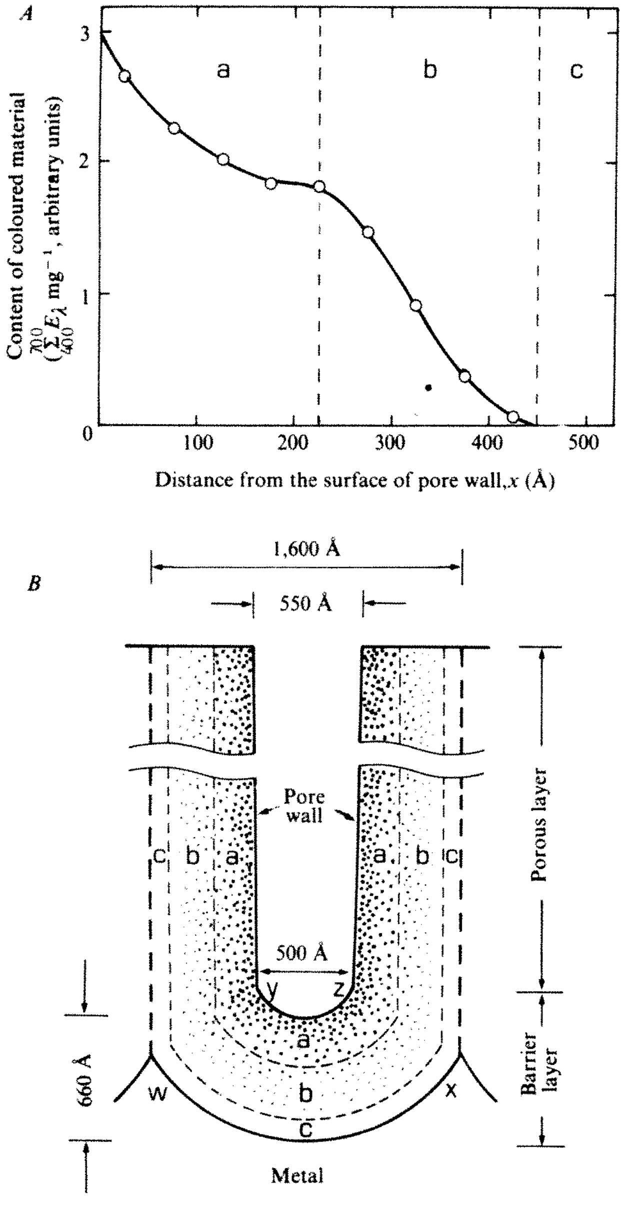

Fig. 3 *A*, The distribution of coloured materials in the porous alumina film formed at 3.0×10^{-2} A cm^{-2} in 0.5 M oxalic acid at 303 K, which is calculated from curve *A* in Fig. 2 by differentiation with the amount of dissolved oxide measured by gravimetry. The coloured materials are located predominantly in the outer region (a, 0–225 Å); decreasing steeply in the next middle region (b, 225–450 Å) and none in the inner region (c, 450–540 Å). *B*, The distribution of coloured materials in the film together with the cell dimensions measured from the electron micrographs.

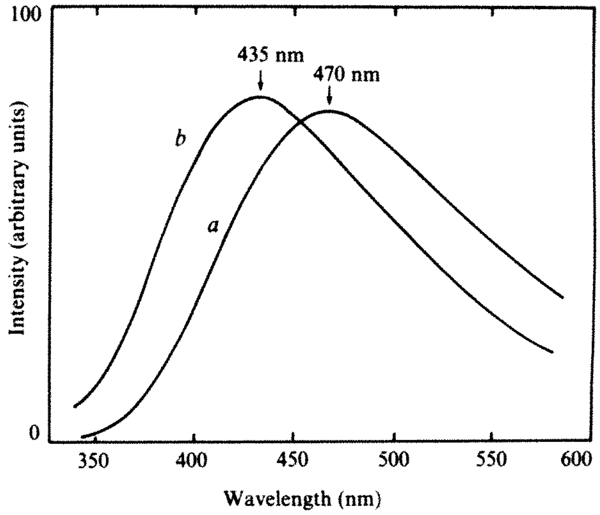

Fig. 4 The emission spectra of the films at different dissolution time when excited with 310 nm: *a*, as-anodized film ($T_d = 0$ min); *b*, the film dissolved for 160 min in 1 M sulphuric acid on open-circuit at 313 K.

Coloured materials and PL centres have different properties as a function of depth of the pore walls of the oxalic acid film. These results suggest that the incorporated oxalate ions which are present in various states within the oxide are converted during anodization. This may be attributed to the inhomogeneous distribution of the electric field across the oxide.

Trace element incorporation into growing augite phenocryst

N. Shimizu

Center for Geoalchemy, Department of Earth and Planetary Sciences, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139

Since the introduction[1] to geochemistry of crystallization theories developed in metallurgy, it has been thought that the effects of kinetic parmeters such as the rate of crystal growth and the rate of diffusive transport of elements in the melt could significantly affect the partition of trace elements between mineral and magma. This conclusion has not, however, been demonstrated unequivocally, mainly because the extent of variations of equilibrium partition coefficients with *T*, *P* and chemistry is not well known. Henderson and Williams[2] found a correlation between morphology and apparent partition coefficient of uranium between olivine and basaltic melt. Data on diffusivity of elements (see ref. 3) and on crystal growth kinetics together with the development of secondary ion mass spectrometry (SIMS) techniques, enable crystal zoning to be studied with respect to trace elements and the kinetic effects to be evaluated quantitatively. Trace element zoning (or lack of it) of minerals is important, as many kinetic-based crystallization models predict trace element zoning in crystals. This letter presents trace element data on a sector-zoned augite phenocryst based on the ion-probe spot analyses. The fact that the slower-growing prism sector [100] is enriched in both compatible and incompatible elements relative to the faster-growing basal sector [$\bar{1}$11] strongly supports Dowty's[4] model for crystal growth involving preferential adsorption of elements onto growing crystal faces in proportion to the charge/size ratio of the elements.

To enhance possible kinetic effects, sector-zoned augite phenocrysts were used, as they present a clear case of disequilibrium crystallization. In a sample of alkali olivine basalt lava (collected by M. Hill from the western foot of Bald Mountain, near Truckee, California) Ti-augite phenocrysts up to 1 × 2 mm in size with very well developed sector zoning occur with olivine and plagioclase phenocrysts in a holocrystalline groundmass. The particular phenocryst studied here has dimensions 0.5 × 1 mm, and a section of this crystal is sketched in Fig. 1. The dark-coloured [100] sector and the pale [$\bar{1}$11] sector share a sharp boundary.

The analytical data were obtained with the MIT–Brown–Harvard Cameca IMS 3F ion probe; the techniques will be described in detail elsewhere, but are similar in principle to those described previously[5]; in particular, energy filtering was used to eliminate molecular ion interferences effectively. A beam of O^- ions with net energy of 13.1 keV was focused to a spot 5–8 μm in diameter on the gold-coated surface of a polished thin section. The secondary ion intensities were measured by an electron multiplier coupled with pulse-counting circuitry, and intensity ratios relative to Si were measured for Na, Mg, Al, Ca, Sc, Ti, V, Cr, Mn, Fe, Co, Sr and Zr. As shown previously[5], the relative intensities of most elements are proportional to their concentrations. Data are presented for some of these as relative intensities; absolute concentrations are reported for those elements for which precise standards and working curves are available.

Traverses consisting of a series of closely spaced points were made at various locations in the crystal (Fig. 1) to study core-to-rim zoning in individual sectors, and to study inter-sector relationships. Data from one of the traverses are shown in Fig. 2. Note that significant differences exist between the two sectors with respect to most of the elements. Also, the [100] sector is homogeneous from core to rim for all elements except Cr. Another traverse shows that the [$\bar{1}$11] sector is also homogeneous from core to rim and that the same outward decrease in Cr is observed. On the basis of Cr variation, this crystal consists of a central region or plateau of high Cr, a marginal region or plain of low Cr and a transition zone in between. These results show that the crystal grew in different directions simultaneously.

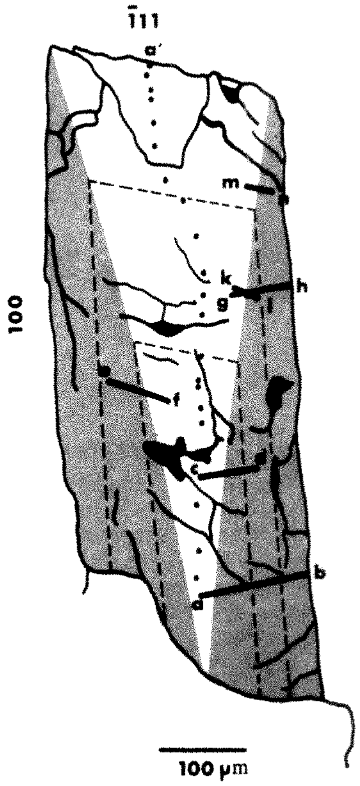

Fig. 1 A crystal of sector-zoned augite. Traverses are labelled a–b, c–d, and so on. A series of points connecting a–a' forms a core to rim traverse of the [$\bar{1}$11] sector. The analytical data along the traverse a–b are shown in Fig. 2. Dashed lines mark approximate locations of the central high Cr plateau, marginal low Cr plain and the transition zone in between (see text).

The most surprising observation is that the slower-growing prism sector [100] is enriched in both compatible (for example, Cr and Sc) and incompatible (for example Ti and Zr) elements relative to the faster-growing basal sector [$\bar{1}$11], even though both sectors are internally homogeneous.

If surface equilibrium was approached during trace element partitioning at the crystal–melt interface, the effect of the faster growth of the [$\bar{1}$11] sector would be to deplete that face in Cr and Sc and enrich it in Al, Ti, Zr, and so on relative to the [100] face. Also, if the overall crystal growth rate was sufficiently rapid relative to the rate of diffusive transport of elements in the magma, an outward decrease of Sc and Cr should be accompanied by an increase of Al, Ti and Zr. Details of these model cases are discussed elsewhere[1]. Neither of these suppositions, which are logical consequences of a simple interplay between the crystal growth rate and diffusion rate, is consistent with the observed data.

An implicit assumption in the crystallization models[6–8] is that interface kinetics are sufficiently rapid compared with diffusivity and the crystal growth, thereby ensuring equilibrium at the crystal–melt interface. However, crystal growth in many glass-forming systems is limited by interface kinetics rather than the rate of removal of latent heat (see, for example, refs 9, 10) and there is evidence that crystallization of silicate minerals from magma is rate-limited by a similar process (see, for example, refs 11–13). Interface kinetics is a loose term which includes processes such as adsorption and desorption, dissociation and chemical reaction, surface and edge migration[14], and we need to consider

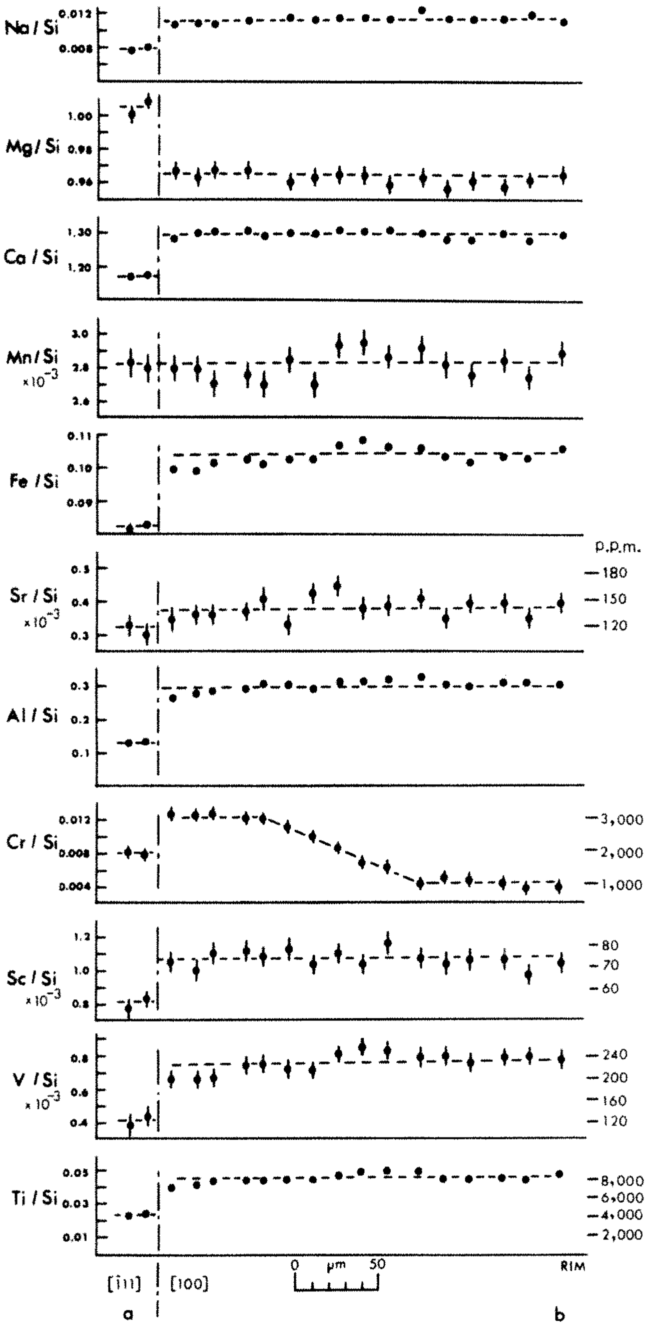

Fig. 2 Analytical data along the traverse a–b. The relative intensities of elements against Si are shown. The concentrations calculated are shown at the right-hand side of the diagram. The error bars represent 2σ counting error. The sector boundary is shown as a vertical broken line.

specific physical processes operating during crystal growth with special attention to the mechanisms of trace element incorporation.

In this context, the model of formation of sector-zoned augite[4,15] has an important bearing on trace element incorporation. The present discussion is essentially an extension of this model to trace elements. The basis of the model is that on the surface of growing augite there is a certain number of cation protosites (which are future M sites), defined by a concentration of negative charges derived from partially bound oxygen atoms, to which cations can be attracted (or adsorbed). In the direction perpendicular to (100) of augite, for instance, there are alternate 'layers' of SiO_3-chains and M_1–M_2 cations; when a new SiO_3 chain is attached, there are several protosites available on the surface to which cations may be adsorbed. If the attachment of SiO_3-chains is rapid, the adsorbed cations are left entrapped; if the attachment is slow, however, the adsorbed elements have time to be desorbed and finally to reach an equilibrium distribution for the given conditions. Thus, the incorporation of trace elements into a growing augite crystal is controlled by two kinetic processes: (1) the attachment kinetics of SiO_3-chains; and (2) the adsorption/desorption kinetics of cations in the protosites. Therefore, for the case of moderately rapid SiO_3 attachment, equilibrium is not expected to be achieved and the degree of adsorption/desorption is expected to be a function of how strongly the cations are bonded to the protosites; the stronger the adsorption, the higher the activation energy of desorption and the slower the desorption, the higher the retention of the adsorbed cations.

Obviously, however, this interrelation of two kinetic processes alone does not account for the fact that the slower-growing [100] sector is enriched in trace elements relative to the faster-growing $[\bar{1}11]$ sector (Fig. 2). A crucial factor here is the number of protosites available in each growth direction. For simplicity, only elements entering the M_1 site, and only the 3/6 and 4/6 types of protosites (see ref. 4) will be considered here. If the growth rate is sufficiently rapid in all directions, the number of atoms adsorbed and then left entrapped will be proportional to the number of available protosites in each direction. Therefore, the [100] sector is expected to take up four times as many atoms as the $[\bar{1}11]$ sector, and the enrichment should be the same for all elements. The actual enrichments in [100] over $[\bar{1}11]$ observed in this study, however, vary between 1 and 2 for the different elements. This suggests that different elements were desorbed from a given sector to different degrees and that desorption was more extensive from the slower-growing [100] sector than the faster $[\bar{1}11]$ sector.

The different degrees of desorption among elements must reflect a difference in the activation energy of desorption (equivalent to a difference in adsorption energy). Figure 3 shows that the preferential enrichment of elements in [100] relative to $[\bar{1}11]$ is proportional to the ratio of the ionic charge of the element divided by the ionic radius squared. The ordinate is a measure of the degree of desorption while the abscissa represents the strength of the Coulomb interaction between a given cation and the protosite. Assuming that the initial enrichment or 'adsorption' factor equals a maximum value of 4 for all elements (based on the relative abundance of protosites), Fig. 3 shows that the stronger the Coulomb interaction, the higher the retention of cations (or the lower the degree of desorption). Dowty[4] suggested that the cations which will be bound most firmly to the protosites are those which have high

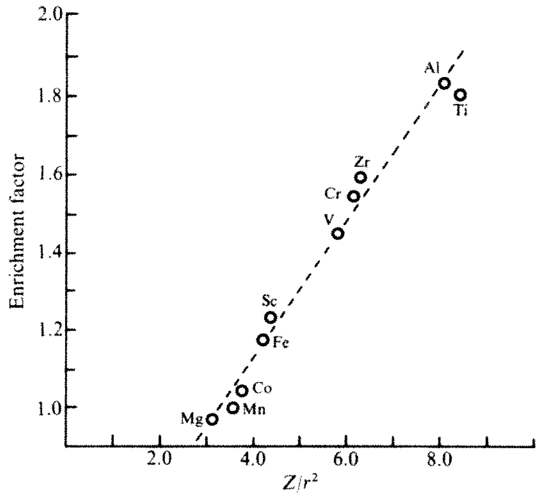

Fig. 3 Preferential enrichment of elements in the [100] sector relative to $[\bar{1}11]$ sector as a function of the ratio of the ionic charge of the element divided by the ionic radius squared. The ionic radii are taken from ref. 16. The correlation coefficient of the points is 0.977.

charges and small size. Figure 3 demonstrates that this relationship holds for 10 elements entering the M_1 site; the Coulomb interaction between cation and protosite is thus the controlling mechanism in this process.

As crystallization conditions (such as the temperature of the magma, the degree of supercooling and the cooling rate of the system) vary from one magma body to another, the relative kinetics of SiO_3 attachment and cation adsorption/desorption are expected to vary, thereby producing different inter-sector element ratios. Conversely, such cation distributions can be used to study different kinetic effects among sector-zoned augites from different areas representing a range of crystallization conditions. A more detailed account of the data presented here, including absolute concentrations of all elements, apparent partition coefficients, and comparison among sectors other than [100] and [$\bar{1}$11], will be published elsewhere.

The present data strongly support the theoretical model of Nakamura[15] and Dowty[4]. The data are not consistent with models such as those given in refs 6–8 which involve an interplay of crystal growth rate and element diffusion rates in the melt adjacent to growing crystals.

I thank S. R. Hart for discussions and comments, also M. Hill for the sample used in this study, K. D. Burrhus for technical assistance, and D. S. Hall for artwork. The work is supported by the NSF grants EAR 7922049 and EAR 8006642.

Plagiogranites from the ocean crust and ophiolites

D. T. Aldiss*

Department of Earth Sciences, The Open University, Walton Hall, Milton Keynes MK7 6AA, UK

Rock types similar to those found in ophiolites have been recovered from the floors of ocean basins[1–3]. This is critical evidence for the theory that ophiolites represent the ocean crust[4,5]. Aumento[6] has described diorites, quartz diorites and trondhjemites dredged from the Mid-Atlantic Ridge (MAR) near 45°N, and noted that these were the first rocks analogous to the low-K acid differentiates in ophiolites (collectively referred to as 'oceanic plagiogranites'[7,8]) to be recognized amongst those recovered from the modern ocean floor. Only a few plagiogranites from the ocean floor (ocean-crust plagiogranites) have since been described; these were dredged from widely spaced localities on the MAR[9–11], the Amani Plateau and the Kyushu–Palau Ridge (north-west Pacific)[12]. However, the Kyushu–Palau Ridge could be the product of destructive plate-margin magmatism[13], as are the potassic granites from the Aves Ridge (Caribbean)[14]. Plagiogranite xenoliths also occur in extrusives on Surtsey and Askja (Iceland)[15]. That only some of the petrological compositions of ophiolite plagiogranites are represented in the ocean crust is not surprising in view of the small sample of ocean-crust plagiogranites. It is less obvious, however, if ophiolites represent the ocean crust, why certain acidic rock types from the oceans have not been found in ophiolites. I show here that the difference between the two groups of plagiogranites is evidence that ophiolites do not represent all kinds of ocean crust and that a greater range of magma compositions and/or conditions of magmatic differentiation is represented by the ocean crust.

Considering that there have been ~500 DSDP boreholes and of the order of 10,000 oceanic dredge hauls, the number of ocean-crust plagiogranites seems very small even compared with the low abundance of plagiogranites in ophiolites[7,8,16,17]. Although the oceanic sample is presumably biased to represent shallow structural levels of the ocean crust, this small number of examples seems to indicate that plagiogranite forms an even smaller proportion of the ocean crust than of most ophiolites.

Plagiogranites from the ocean crust and those from ophiolites are generally similar in essential primary mineralogy (predominantly sodic plagioclase with quartz and hornblende), in secondary minerals and textures and in major element geochemistry (plagiogranites are characterized by $K_2O < 0.7\%$ and the more silicic are relatively depleted in Fe, Ti, P and K and more enriched in Na)[1,6–11,17].

However, there are differences in accessory mineralogy and alkali and trace element geochemistry between some ocean-crust plagiogranites and typical ophiolite plagiogranites. Except in some large (few kilometres diameter) plagiogranite stocks and aplites which intruded some ophiolites at a late stage in their development[17,18] and the Byne Hill (Ayrshire) trondhjemite[19], K-rich minerals (biotite and so on) are virtually absent from ophiolite plagiogranites[7,8,16,17]. I have found rare secondary

allanite in an epidote–quartz metamorphite from the Troodos Massif (Cyprus) but know of no other occurrence of this mineral in an ophiolite. However, a diorite from the MAR at 45°N has rare K-feldspar cores, minor biotite and allanite[6]. Elsewhere on the MAR, biotite dominates hornblende in a quartz diorite from 0°N (ref. 9) although plagiogranites from 22° S resemble typical ophiolite plagiogranites in every descriptive detail[10]. Plagiogranite xenoliths from Surtsey have minor K-feldspar and relatively high K_2O (ref. 15).

Some granitoids from the ocean-crust are not plagiogranites. A specimen of leucoquartz monzonite (ANTP 125-4) dredged from the Argo Fracture Zone, Central Indian Ridge[20,21], contains essential K-feldspar and also has high Rb, Nb and Y and low K/Rb, relative to ophiolite plagiogranites. Two aplites from the Argo Fracture Zone also have high Nb and Y (Table 2). The only similar rocks from any ophiolite are late alkalic aplites which intruded gabbros of Masirah Island, North Indian Ocean, and which are believed to have originated in continental crust[22].

Four of the quartz diorites from the MAR at 45°N were analysed for rare earth elements (REE), Th and Ta. They are light REE (LREE) enriched and also have a greater abundance of incompatible trace elements than representative ophiolite plagiogranites (Table 1, Fig. 1). The REE pattern[21] of ANTP 125-4 is similar to that of the quartz diorites although with a more pronounced Eu anomaly. Ophiolite plagiogranites are normally LREE depleted although they also have negative Eu anomalies[7,8,17,23] (Fig. 1). These contrasts in trace element content could be attributed to regional differences in either magma composition or magmatic differentiation. (Hydrothermal metamorphism, although an important petrogenetic factor in ophiolites and the ocean crust[24,25], is thought not to change the distribution of the REE[26,27]). Although basalts enriched in LREE and other large ion lithophile elements have been found on the MAR at 45°N, as well as the usual LREE depleted varieties[28], basic rocks associated with the Argo Fracture Zone granitoids are all LREE depleted[21]. Therefore primary magma composition need not be the controlling factor. Relative LREE-enrichment of ANTP 125-4 has been attributed to apatite fractionation[21] and more advanced differentiation could also account for its enrichment in other incompatible trace elements.

†Quartz diorites, tonalites, trondhjemites and aplites from the Troodos Massif, Cyprus, the Semail ophiolite, Oman and the Smartville Block, California[8,17].

It seems therefore that some ocean-crust plagiogranites cannot be distinguished from typical ophiolite plagiogranites and that their similarities are greater than their differences. This supports the contention that ophiolites represent ancient ocean crust. However, the mineralogical and chemical variety of granitoids discovered in the present-day ocean crust exceeds that found in ophiolites although the actual number of examples is much smaller, suggesting that a greater range of physical and/or chemical conditions pertained during the formation of the ocean crust. It also implies that ophiolites are a sample of a limited number of types of ocean crust. I look forward to descriptions of comparative material from a modern marginal basin or juvenile island arc.

I thank Dr F. Aumento for samples of quartz diorite, the NERC for support, Professor I. G. Gass for supervising my research studentship, Dr Phil Potts for help with REE analysis, and Drs R. G. Coleman and N.M.S. Rock for helpful criticisms.

Lower Cretaceous tides revealed by cross-bedding with mud drapes

J. R. L. Allen

Department of Geology, The University, Reading RG6 2AB, UK

The sand-dominated Folkestone Beds, widely exposed around the Weald of south-east England, are of Upper Aptian to Lower Albian (Lower Cretaceous) age and range in thickness up to 84 m (refs 1–3). Their content of ammonites, bivalves and sponges indicates a marine origin, while their relative coarseness and the incorporation of drifted timber point to a shallow water deposition near land. One striking sedimentary facies is formed by medium to coarse-grained cross-bedded sands in which several foreset and/or bottomset surfaces support mud drapes. Although it was suggested[4] that this facies may have been formed by the storm-induced movement of sand waves, I now consider that the facies is best explained by the migration of sand waves under the influence of strongly asymmetrical tides, and that the mud drapes are formed at slack water. A model of this process has been described elsewhere[5] and I now describe measurements of a section which supports my earlier conjecture[6] that the separation of the mud drapes is systematically related to the phase of the spring–neap tidal cycle at the time of deposition. Although criteria for recognizing tidal deposits have long been available it has not previously been possible to analyse a series of ancient sediments with a view to characterizing the tidal regime.

Measurements were made of a 22.9-m long portion of a typical cross-bedding set exposed on a smooth vertical face of the Pendean Sand Pit near Midhurst, Sussex (SU 890 200; operated by Hall Aggregates (South Coast) Ltd). The set is bounded above and below by nearly horizontal surfaces corresponding with erosion levels. The set shows groups of sandy foresets–bottomsets (taken to correspond with episodes of sand transport and deposition) alternating laterally with much thinner mud drapes (corresponding with episodes of mud deposition). The mud drapes are rarely thicker than a few millimetres, although locally several may be piled on each other to make a thick mud layer. Many of the mud drapes have one or—rarely—more internal silty or sandy partings. The extent of a drape as revealed on the quarry face is variable, Fig. 1 showing a schematic profile in the cross-bedding set.

The measured set is ~2 m thick. The foreset azimuth is nowhere greatly different from the trend of the face (15°–195°) so that the measured thickness of each sand deposit (group of foresets) is very nearly its true thickness in the direction of the tidal stream at deposition. The 22.9-m section includes 65 groups of sandy foresets and 66 intervening mud drapes of different extent (classified as short, medium and long, Fig. 1). The apparent thickness (d) of the successive groups of sandy foresets is shown in Fig. 2, together with the estimated extent of the intervening mud drapes.

The marked periodic variation of the thickness d in the records of Fig. 2 accounts for the way in which field observation shows the mud drapes to be bunched or bundled together—bunching occurs where the sandy foresets are thinnest. The section I have measured includes four complete cycles (numbered 2–5) (including 32, 28, 16 and 30 episodes) and parts of two other cycles (cycles 1 and 6 in Fig. 2) including at least 18 and 6 episodes respectively. The complete cycles are consistently asymmetrical, thickness increasing more quickly than it decreases. On descending limbs there usually occur alternately thick and thin sand deposits (for example, episodes 64–78, 84–94, 100–124 all inclusive). A further 28 cycles (24 counted, 4 estimated) lie in the contiguous downstream extension of the same set. The longer and thicker drapes (A–E on Fig. 2) tend to be associated with, or lie just upstream from, the thinner sand deposits.

It has been proposed[5] that the formation of this facies was dependent on a subtidal sandwave influenced by a strongly asymmetrical tide. The variation of stream speed in such a cycle (of length T) is shown in Fig. 3 Asymmetrical tidal patterns may arise in shallow water because of the distortion of the tidal wave, or because of the presence of a steady current, which may be caused in several ways, or both.

The instantaneous rate of mud deposition (mass per unit area of bed surface) from such a stream may be written[7] as

$$\frac{\mathrm{d}m}{\mathrm{d}t} = \sigma C W (1 - U^2/U_{\mathrm{cdm}}^2); \; U \leq U_{\mathrm{cdm}} \qquad (1)$$

where m is the mass per unit area, t is time, σ is the density of mud solids, C the fractional volume concentration of mud in the water, W the falling velocity of mud particles, U the vertical average of current speed, and U_{cdm} the speed above which mud deposition does not occur evaluated at the same roughness as U.

Figure 3 also shows the two critical stream speeds on which our model depends. These are U_{cdm}, the critical speed below which mud deposition can occur, and U_{ces}, the critical speed above which bedload sand movement occurs. U_{ces} is greater than U_{cdm}.

Over a tidal cycle (Fig. 3), mud will accumulate during the intervals $(t_5 - t_4)$ and $(T - t_6 + t_1)$, where T is the tidal period. But as the tidal streams are asymmetrical, but at times exceed the threshold for bedload sand movement, U_{ces}, between t_5 and t_6, the two accumulations should tend to appear as one in the field, with the strong possibility that a silty or sandy parting may be formed, due either to the mobilization of grains at the sand-wave crest or continued fall-out of bed material during the peak stream following t_5. This explains the partings seen in the field within many drapes. Moreover, as U_{cdm} is of the order of 0.05–0.10 m s^{-1}, the mere presence of the drapes implies that the tide was not significantly rotary and that the cross-bedding set therefore accumulated in restricted waters, either near shore, in an estuary, or within a strait. Integration of equation (1) over the relevant parts of the tidal cycle shows that the drapes should be thickest and longest when the peak tidal currents are relatively gentle (other factors remaining constant), for $(t_5 - t_4)$ and $(T - t_6 + t_1)$ are then maximized. This tends to occur when the sand deposits take their smallest apparent streamwise thickness.

The spatially-averaged instantaneous bedload sediment transport rate beneath a tidal stream fashioning sand waves is approximately described kinematically by

$$J = k(U - U_{\mathrm{ces}})^3, \qquad U \geq U_{\mathrm{ces}} \qquad (2)$$

in which J is the mass carried down a lane of unit width in unit time, and k a dimensional constant set by sediment and flow characteristics[5,8,9]. Hence the true streamwise thickness of the sand deposit formed during one tidal cycle (Fig. 3) is

$$d = \frac{2k}{H\gamma} \int_{t_2}^{t_3} [U(t) - U_{\mathrm{ces}}]^3 \, \mathrm{d}t, \qquad U \geq U_{\mathrm{ces}} \qquad (3)$$

in which H is the sand-wave height, and γ the sand bulk density.

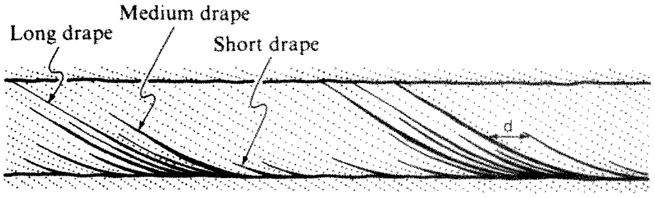

Fig. 1 Schematic representation of cross-bedding set with bundles of mud drapes (individual drapes distinguished as short, medium or long).

0028–0836/81/070579–03$01.00

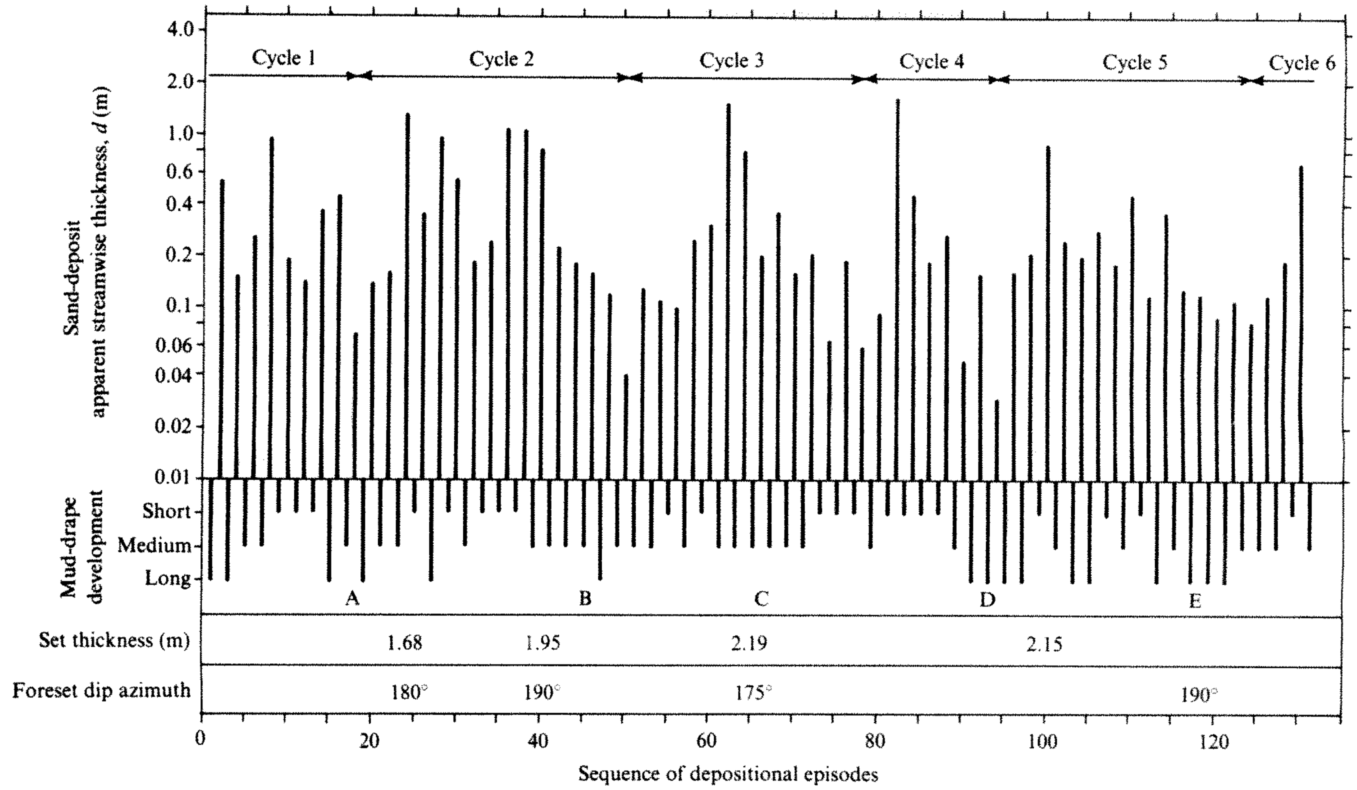

Fig. 2 Sand-deposit apparent streamwise thickness (d) and mud-drape development as a function of time (depositional episodes) in a cross-bedding set at Pendean Sand Pit near Midhurst.

Because J is a steeply increasing function of the speed difference, a small change in the peak speed of the tidal current should create a large change in the sand-deposit streamwise thickness. Applied to the Pendean thickness record (Fig. 2), equation (3) points to a substantially regular variation in the maximum speed of the tidal currents that deposited the set, the weaker peak streams, yielding the thinner layers, occurring at about the same time as, or a little after, the interval when most mud settled out. The observed antisymmetrical behaviour of the mud and sand deposits is thus fully explained by the model, although many factors, such as a change in mud concentration, the growth of wind waves and a resultant increase in bottom stress and inhibition of mud deposition, or the superimposition of storm currents on the tidal stream, may have disturbed its theoretical regularity. Could the slight asymmetry of the sand thickness cycle be related to bed-hardening consequent on extensive mud deposition and ageing[10] as the peak tidal currents declined towards the neaps?

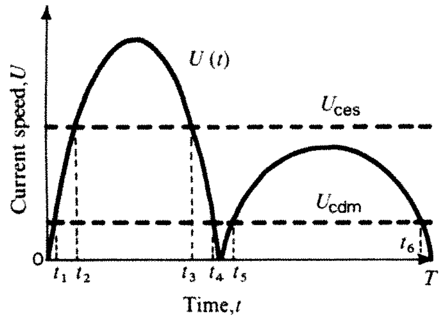

Fig. 3 Schematic time–speed pattern for tidal currents during one tidal cycle of the general kind thought to generate strongly asymmetrical sand waves (note that bedload transport is restricted to one half of the cycle only in the specific instance graphed; in some cycles U_{ces} may be exceeded slightly by the weaker stream).

The above factors may also account for the slight lack of uniformity in the period of sand thickness variation, for the suppression of just a few mud drapes would drastically cut the number of detectable depositional episodes (? cycle 4). Alternatively, during some neap tides the peak stream may never have equalled U_{ces} in speed, when no sand deposit would have resulted. The observed preferred period of 28–32 episodes strongly suggests that the thickness cycle records a spring–neap tidal periodicity (thick layers ≡ spring tides; thin layers ≡ neaps) involving tides of the diurnal type[11], a bidiurnal inequality (unknown in present-day tides) being strongly suggested by the regularly declining sequences of alternately thick and thin foreset groups (see, for example, episodes 64–78). Alternatively, the tide could have been semidiurnal, but with many flows failing to reach the sand movement threshold. This interpretation is thought less likely, because in association with the thinner sand deposits there are inadequate numbers of thick mud drapes including more than one sand–silt parting. That the period inferred from the Lower Cretaceous Folkestone Beds is a little larger than that measured today is consistent with palaeontological and other evidence[12–14] for a gradual and slight reduction through time in the number of days in the year. Sedimentological evidence for this change has not previously been available.

Careful analysis of the pattern of lithological change (or reactivation) in sand-wave deposits, can infer much about the character of ancient tides. In the case of the Folkestone Beds, in which there are cross-bedded sands with mud drapes, the tide seems to have had a strong time–velocity asymmetry, permitting only one episode of sand movement in each tidal cycle, and to have been diurnal with a comparatively small bidiurnal inequality. The apparent spring–neap cycles are of unequal duration, however, suggesting that the lack of some sand layers was due either to the suppression of mud deposition or to a sand transport threshold which for some tides was in excess of the peak speed. The tide had little or no rotary character, a conclusion demanding the restricted seas independently demonstrated for the Folkestone Beds[2,3]. Because time can now be measured from them, we can now be certain that the cross-bedded deposits of the Folkestone Beds represent vastly shorter periods of time than the erosion surfaces which lie between the sets.

I thank J. L. C. McIntyre and R. A. Collins for the opportunity to work at their Pendean Sand Pit.

Plutonium transport to and deposition and immobility in Irish Sea intertidal sediments

S. R. Aston* & D. A. Stanners*

Department of Environmental Sciences, University of Lancaster, Lancaster LA1 4YQ, UK

The deposition and possible mobility of plutonium in sediments contaminated by nuclear fuel reprocessing wastes are of considerable importance in assessing the short- and long-term fate of this pollutant. Previous studies have shown that marine sediments very effectively and quickly remove plutonium[1], and have suggested both immobile[2] and mobile[2,3] behaviour of plutonium after deposition. Here, the deposition characteristics and lack of vertical migration of plutonium isotopes in intertidal sediments of the Irish Sea, which are contaminated with radioactive wastes from the Windscale reprocessing facility, are discussed.

Plutonium isotopic composition profiles in the accumulating sediments show that plutonium deposition is controlled by the physical deposition of contaminated sediment particles, and the total plutonium activity profiles reflect the general pattern of changes in the quantities of Windscale plutonium discharged. The use of the ^{238}Pu/$^{239+240}$Pu ratios in sediment profiles to estimate sedimentation rates agrees well with the rates measured using independent fission product profiles. These plutonium isotope ratio profiles suggest that plutonium vertical redistribution in the sediments is exceedingly small. When the apparent diffusion rate (which encompasses all diffusive and advective processes) for plutonium is calculated[4,5], a very small apparent diffusion coefficient D must be invoked for the best fitting of previously measured sediment surface ^{238}Pu/$^{239+240}$Pu ratios[6] to those now observed at various depths in the sediments. While changes in the isotopic ratios are well preserved in the sediments after deposition, the peak in the total concentration of plutonium at depth in the dated sediments is found in sediment layers which were deposited ~2–3 yr later than the peak plutonium release from Windscale was discharged. This feature may be a consequence of the time required for the plutonium to travel from the pipeline to the sediments, or of an exchangeable pool or available pool of sediment in the Irish Sea which has a finite clearance rate for the whole Irish Sea basin. The plutonium in these sediments is mostly associated with iron/manganese non-detrital phases and does not undergo diagenetic changes in the oxic sediments.

Sediment cores were collected during mid-1978 from the intertidal reaches of the River Esk, Ravenglass Estuary, eastern Irish Sea, ~10 km south of Windscale[5–7]. Cores were extracted and divided into segments, the plutonium was extracted and radiochemically separated for electrodeposition and α spectroscopy[8]. Fission products in the sediments were determined by γ spectroscopy.

Table 1 shows the ^{238}Pu and $^{239+240}$Pu activities measured in three cores of intertidal sediments together with the profiles of the isotopic ratio ^{238}Pu/$^{239+240}$Pu. Maximum plutonium activities for both ^{238}Pu and $^{239+240}$Pu occur at depths of 3, 3 and 13 cm in cores E-1, E-2 and E-3 respectively. In core E-3 a minor peak in plutonium activities is also found at 36–42 cm. The ratio of ^{238}Pu/$^{239+240}$Pu decreases from surface values of ~0.25 to <0.14 as sediment depth increases. In an earlier investigation of plutonium in sediments from the same field site, Hetherington[1,6] found an approximately exponential increase in plutonium activities towards the surface of the sediment profiles. Hetherington's cores were collected in 1973 and he attributed the profiles to the deposition of contaminated particles which reflected the continuously increasing annual discharge of plutonium from Windscale. The contrasting pattern of plutonium deposition found in the present study is easily accounted for by the decrease in the plutonium discharges from Windscale since 1973.

The total ^{238}Pu and $^{239+240}$Pu activities discharged over the period 1970–78 were 936, 1,128, 1,548, 1,776, 1,248, 1,195, 1,272, 984 and 1,572 Ci yr^{-1} respectively[6,9]. The present core profiles show that the general features of the continuing temporal pattern of plutonium discharge are preserved within the intertidal sediment profiles. The presence of 'buried' plutonium peak activities within the cores confirms that the physical sedimentation of contaminated grains is the overall mechanism of plutonium deposition. Hetherington's data[6], with its increasing plutonium activities towards the sediment surfaces did not definitively show this because the 1973 profiles can be interpreted as being produced by an upward vertical migration of plutonium through the sediment. Plutonium profiles in sediment cores from nearshore, continental shelf and continental slope areas of the eastern US have been attributed to biological mixing and chemical mobilization processes[2,3]. The upward translocation of plutonium in sediments, and the importance of bioturbation on fallout plutonium in slowly depositing nearshore sediments, have been emphasized[3]. However, it has been pointed out that these conclusions cannot be extended to regimes with higher sedimentation rates. The present intertidal areas are ones of high sediment accumulation, and these net rates have been determined as 16, 16 and 65 mm yr^{-1} (±15%) for cores E-1, E-2, E-3 respectively using fission product isotopic ratios[5]. Using a similar technique[5] for the plutonium isotopic ratio in which the sediment profile and previously measured surface sediment ratios (Table 2) are matched by an optimization routine for least squares fitting with an assumed range of net sedimentation rates, the respective rates were 13, 10 and 62 mm yr^{-1}. This shows good agreement with the independent fission product method. An important point in the technique is that the best agreement was achieved when the apparent diffusion coefficient for the plutonium in the sediments was set at $D < 10^{-12}$ cm^2 s^{-1}.

This information is used here to argue that plutonium translocation is very small in these sediments, and the data shown in Table 1 when interpreted in the context of these sedimentation rates indicate that there is a finite time lag of 2–3 yr between the

plutonium discharge from Windscale and the arrival of plutonium in the sediments. The data indicate that although the general response to increasing and decreasing discharges is reflected in the overall pattern of deposition, the peak activities are delayed either by a slow transit time from Windscale or because of the clearance time for sediments in the Irish Sea basin. In either situation, the fact that plutonium is very rapidly and effectively removed to sediments[1] is consistent with the slow movement of plutonium in association with bottom sediments rather than with the water masses. Other radioisotope transit or delay times from Windscale to the sampling site have been reported as ~1 month (^{106}Ru, ^{144}Ce)[7], 2–3 months ($^{95}Zr/Nb$)[7] and ~1.5 yr (^{134}Cs, ^{137}Cs)[10]. Clearly the different chemical natures of the radionuclides in the marine environment influence their rates of movement in coastal waters.

Environmental processes are extremely unlikely to differentiate ^{238}Pu and $^{239+240}Pu$, and this allows the isotopic ratio to be used to specify the 'age' of plutonium in a sediment layer. Relatively early discharges of plutonium from Windscale, for example, pre-1968 discharges were significantly smaller than those in more recent years[9,11], and exhibited characteristically low $^{238}Pu/^{239+240}Pu$ ratios. Table 2 shows the $^{238}Pu/^{239+240}Pu$ ratios in surface (<1 cm) sediments from the River Esk estuary as an indication of the changing isotopic composition up to the present higher ratios of ~0.25. The preservation of the older low ratios at depth in the cores with their low plutonium activities (Table 1) further suggests and thus supports the above interpretation that mobilization and vertical mixing with sediments containing greater activities and higher $^{238}Pu/^{239+240}Pu$ ratios is negligible. The intertidal sediments are occasionally bioturbated by populations of *Corophium volutator* (Pallas), but the mixing depth that is the extent to which the organisms may move radionuclides and other substances associated with sediment grains[12,13], seems to be less than the annual increments of sediment accumulation at this location, and does not give rise to any effective vertical movement of radionuclides.

Table 2 The ratio of $^{238}Pu:^{239+240}Pu$ activities in surface (<1 cm) intertidal sediments of the River Esk estuary between 1966 and 1975[6]

Year	$^{238}Pu/^{239+240}Pu$	Year	$^{238}Pu/^{239+240}Pu$
1966	0.053	1972	0.196
1967	0.067	1973	0.200
1968	0.074	1974	No data
1969	0.100	1975	0.238
1970	0.116		
1971	0.185		

Data on the annual $^{238}Pu/^{239+240}Pu$ discharge ratio are not available for this time period.

Theoretical arguments[14] have been used to show that plutonium in marine particulates should be in the Pu (IV) state as insoluble hydroxides, probably in association with iron and manganese oxide/hydroxide colloids. This is strongly supported by the field observations on the Pu (IV) oxidation state in suspended solids in the Irish Sea[15]. A chemical leaching technique[16] was applied to the present sediment cores, and the results showed that 75–100% of the plutonium was in the non-detrital iron/manganese phases. The proportion of plutonium in these phases varies with depth, but there is no apparent trend with depth indicating a lack of diagenetic change in plutonium phase association after deposition. These results agree well with data on fallout plutonium in lacustrine and coastal sediments[17].

From the present results we conclude that: (1) The deposition of contaminated sedimentary particles is the principal control of plutonium input to intertidal sediments in the Windscale area, confirming Hetherington's earlier hypothesis[1,6]. (2) A transit time or clearance rate in the sediment pool of the Irish Sea basin delays the deposition of plutonium at the study site by 2–3 yr. (3) The activities of plutonium and the $^{238}Pu/^{239+240}Pu$ ratio in vertical profiles suggest that post-depositional migration of this pollutant is negligible (apparent $D < 10^{-12}$ cm^2 s^{-1}). (4) The plutonium is mainly in the non-detrital iron/manganese phase, and there is no evidence for diagenetic changes in phase association after burial in the oxic sediment layer.

We thank the NERC for financial assistance, the Fisheries Radiobiological Laboratory, MAFF (Lowestoft) for use of facilities, and M. Kelly and D. J. Assinder for helpful comments.

Function of the mandibular tooth comb in living and extinct mammals

Kenneth D. Rose & Alan Walker

Department of Cell Biology and Anatomy, The Johns Hopkins University, School of Medicine, Baltimore, Maryland 21205

Louis L. Jacobs

Museum of Northern Arizona, Flagstaff, Arizona 86001

Among the most interesting mammalian dental specializations is the mandibular 'tooth comb' or 'tooth scraper' that evolved independently in certain primates and other mammals. Its occurrence is most widely known in lemurs and lorises, where it is comprised of the long, slender, procumbent incisors (one or two pairs) and incisiform canines (Fig. 1). In non-primates the canines are not incorporated into the comb. Some tree shrews (Tupaiidae) possess a tooth comb consisting of the four central incisors, and some early Tertiary arctocyonid condylarths had a similar structure composed of all six lower incisors[1]. The extant flying lemurs (Dermoptera: *Cynocephalus*) also have a dental 'comb' but it is very different from the ones already mentioned, consisting of two pairs of pectinate incisors, each tooth modified into a comb with as many as 15 tines. This condition, although sometimes said to be similar to that in lemurs, is unique to *Cynocephalus*. One of the principal functions of the tooth comb in primates is to comb the fur, and we present here indirect evidence that condylarths used this structure in the same way, millions of years before tooth combs evolved in prosimians. We also show that the comb-like incisors of *Cynocephalus*, contrary to popular belief, probably do not function to comb the fur.

The function of the mammalian tooth comb has been controversial. Its comb-like appearance in prosimian primates led very early to the suggestion that it is used in grooming the fur[2], a hypothesis that persisted unchallenged for more than a century[3–6]. Some authors have doubted[7] or even denied[8] such a function for the tooth comb, but behavioural studies have confirmed its use during grooming[9–12]. Tupaiids have been reported to use their tooth combs for grooming in the same manner as do lemurs[6]. It is now recognized that grooming is not the sole function of the prosimian tooth comb. Several smaller lemurs and lorises (for example, *Phaner furcifer, Euoticus elegantulus* and *Galago senegalensis*) use this structure in procuring gum[13–15], and the sifaka, *Propithecus verrauxi*, uses its comb to gouge bark and dead wood, particularly in the dry season[16,17]. Some lemurs (such as *Microcebus murinus, Propithecus verrauxi* and *Indri indri*) scoop fruit pulp with their dental combs[12,18].

There has been disagreement as to whether prosimians, when grooming, use their tooth combs to comb the fur or merely to scrape it. Buettner-Janusch and Andrew[12] found fine hairs caught between the incisors of *Galago* after grooming—compelling indirect evidence of combing. One of us (A.W.) has observed hair-combing with the tooth comb in several captive lemurs and lorises. Martin[18], citing observations of R. Every, reported that teeth in the comb of lemurs bear " 'whip marks' produced by hairs pulled between the teeth".

Using scanning electron microscopy (SEM) to examine teeth from prosimian combs, we have confirmed the presence of fine vertical grooves (~10–20 μm wide, also visible with the light microscope), presumably made by hairs, on the lateral and medial sides of the teeth and on their median dorsal (lingual) ridges (Figs 1, 2). The grooves are discontinuous, being absent from the intervening concave surfaces between the sides of each tooth and the median ridge. Within these grooves are long, finer microstriations (<1 μm wide), which may have resulted from scratching by the cuticular layer of the hair. Similar grooves are visible on the incisors of some tupaiids (for example, *Tupaia glis, Tupaia tana*).

When did the prosimian tooth comb evolve, and for how long has it been involved in grooming? There is no tooth comb in early Tertiary Adapidae (considered the oldest lemuriform primates by many authors), although one species, *Adapis parisiensis*, shows modifications of the lower anterior teeth that may foreshadow a tooth comb[19]. Aside from adapids, the oldest known lemuriforms are early Miocene lorisoids from East Africa[20,21] and late Miocene lorisoids from Asia[22]. Crowns of the anterior teeth are not yet known for early Miocene lorisoids, but the configuration of canine and incisor roots in some specimens indicates that the tooth comb was fully developed by that time[23]. The most ancient lorisoid in which the crowns of the comb teeth are known (and also the only fossil one in which they are known) is *Nycticeboides simpsoni* (holotype, YGSP 8091) from the Siwalik Group, Pakistan, probably between 7 and 8 million years old[22,24]. These comb teeth, including the crowns of

one canine and two incisors, are morphologically very similar to corresponding teeth in modern lorises and galagos. Scanning electron micrographs of these comb teeth reveal grooves (10–15 μm wide) and finer scratches (<1 μm) remarkably similar to those formed on the comb teeth of modern lorisoids that use the tooth comb for grooming (Fig. 2). Thus it seems that grooming behaviour like that performed by extant lorisoids had evolved by the late Miocene. The type specimen of *N. simpsoni* documents, therefore, the earliest record of tooth comb grooming behaviour in prosimian primates.

Gingerich and Rose[1] reported the occurrence of a lemur-like tooth comb in an earliest Eocene (Clarkforkian) arctocyonid condylarth (cf. *Thryptacodon* from Wyoming) and postulated that it functioned in grooming. SEM examination of this specimen reveals the presence of closely spaced fine grooves (~25 μm wide), virtually identical in size and form to those on prosimian comb teeth (Fig. 1). These grooves indicate that *Thryptacodon*, like lemurs, combed its fur with its tooth comb.

A recently discovered specimen of a middle Palaeocene (Torrejonian) arctocyonid from Montana possesses a tooth comb like that in the Eocene specimen, but with larger incisors that are more heavily worn. SEM examination of this specimen also reveals grooves on the sides and median dorsal ridge of the incisors (Fig. 1). That these grooves formed during life is demonstrated by their continuation across the enamel edges and dentine exposure of the median dorsal ridge of each incisor. The

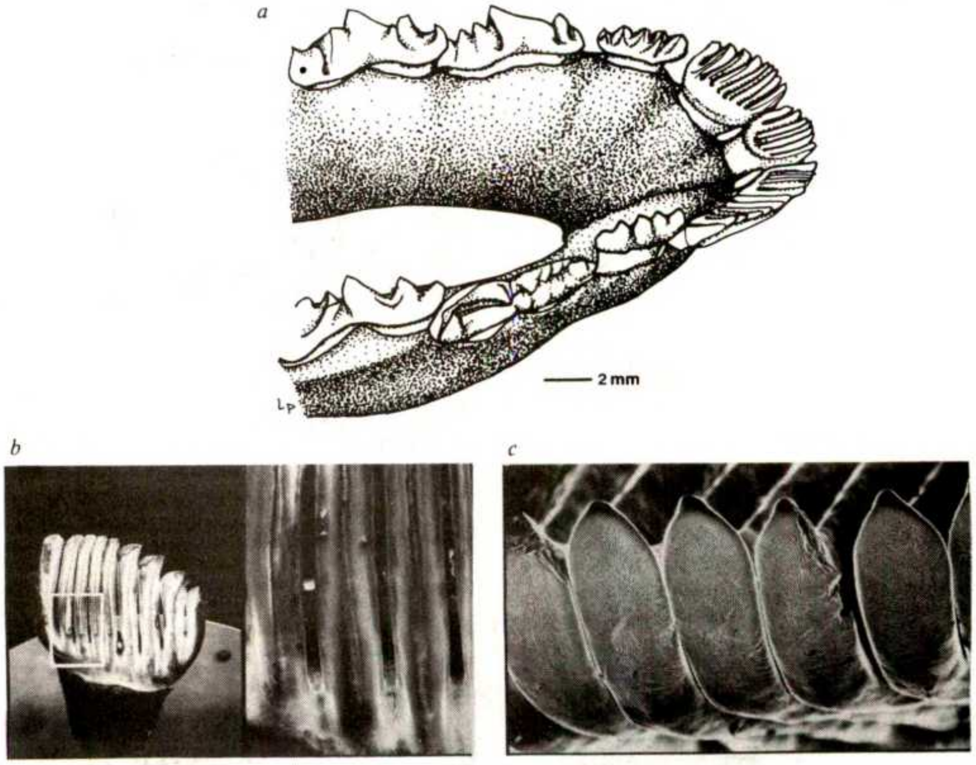

Fig. 3 *a*, Drawing of the anterior dentition of *Cynocephalus variegatus*, showing comb-like incisors. *b*, Scanning electron micrographs of a central incisor of *Cynocephalus* (left). Note that no grooves are evident between the tines of the tooth. *c*, Scanning electron micrograph of labial apical facet on incisor of *Cynocephalus*, showing exposure of dentine tubules.

grooves on these teeth are considerably broader (~100 µm wide) than those on the incisors of cf. *Thryptacodon*, and probably represent the coalescence of several smaller grooves—a consequence of much heavier wear in this specimen.

Early Eocene (Wasatchian) specimens of the arctocyonid *Chriacus* from Wyoming also possess an incisor comb very similar to that in cf. *Thryptacodon* and, similarly, minute grooves can be detected on the sides of the incisors[25].

These arctocyonid specimens document the earliest known occurrence in the mammalian fossil record of grooming with a dental comb, predating the oldest evidence of a tooth comb in fossil primates by at least 40 Myr. They may represent three different genera of smaller arctocyonids, suggesting that fur-combing with the incisors was an important behavioural trait in several early Tertiary condylarths.

Recently primatologists have concentrated on the question of the original function of the tooth comb. Martin[18,26] proposed that the tooth comb initially functioned in procuring gum, especially in smaller species, and that grooming was a secondary function. Other authors have contended that the comb must have evolved primarily as a grooming apparatus[12,27]. The arctocyonid tooth combs described above are relevant to this problem. Grooming was clearly performed by even the oldest mammal (middle Palaeocene) known to possess a tooth comb, but this form also shows heavy wear of the incisors, especially at the apices. The tips of the incisors seem to have formed a single cutting edge, similar to the condition in bark-gouging primates such as *Propithecus*. Thus the oldest available evidence indicates that the tooth comb functioned for both grooming and food procurement. The specimen of cf. *Thryptacodon* is less worn than the Palaeocene specimen, and its incisors are relatively longer and more slender. Moreover, they are pointed at the tips, as in *Lemur*, and do not form a single cutting edge. Eocene *Chriacus* resembles cf. *Thryptacodon* in these features. Thus, in cf. *Thryptacodon* and Eocene *Chriacus*, food procurement may have become subordinate to grooming, or may no longer have been a significant function of the tooth comb. The question of whether gum-eating or grooming was the earliest function of the combs of the ancestors of lemurs and lorises is still unanswered, as even those species that eat gum today seem to have no distinctive wear resulting from that activity.

The function of the comb-like incisors of *Cynocephalus* (Fig. 3) is unclear, but it has been widely stated that they, too, are used to comb the fur[28-30]. A few authors disagree with this view[8] or consider that grooming is not the principal function[31,32], and we know of no documented observations of flying lemurs using their incisors for combing. Indeed, Wharton[33] reported that *Cynocephalus* grooms by licking its fur; he did not mention use of the incisors—the incisors probably serve in food procurement. *Cynocephalus* is strictly herbivorous, feeding largely on leaves, blossoms and fruits[30,33,34], and it has even been suggested that the incisors are used for 'scraping the green colouring matter out of leaves'[35]. Though this is difficult to substantiate, stomach contents we examined were dominated by small bits of leafy matter, confirming Wharton's[33] observations. The lower incisors may function to crop leaves against the edentulous part of the premaxilla (as in many artiodactyls)[36], or to scrape leaves[29].

Our SEM examination of incisors of both extant species of *Cynocephalus* (*C. volans* and *C. variegatus*) revealed no evidence of the fine grooves seen on incisors of lemurs, lorises, tupaiids and arctocyonids, and inferred to be caused by hair-combing. A wear facet is present on most specimens on the labial (ventral) side of the tooth, at the apices of the tines. It probably results from contact with the edentulous part of the premaxilla and is consistent with a cropping function for the dermopteran tooth comb. The precise function of the elaborate tooth comb of *Cynocephalus* remains uncertain, but it seems very unlikely that this apparatus, the most comb-like of such structures, is actually used to comb the fur.

We thank D. Baird, P. Gingerich, M. Lambert, D. Pilbeam, R. Thorington, M. Turner, and the Director, Geological Survey of Pakistan, for access to specimens used in this study, and Linda Perez and Gary Morgan for technical assistance. This work was supported by NSF grant BNS 78-24499 to A.W.

Miocene lorisid primates from the Pakistan Siwaliks

Louis L. Jacobs

Department of Geosciences, University of Arizona, Tucson,
Arizona 85721 and Museum of Northern Arizona,
Flagstaff, Arizona 86001

In 1975–79, joint expeditions from Yale University and the Geological Survey of Pakistan (YGSP) recovered fossil lorisids in the Siwalik Group of Pakistan from four localities, spanning a period before 10 Myr ago to about 7 Myr ago[1,2]. In three of the localities, only isolated teeth or fragments were found, whereas the fourth and youngest locality yielded dental, cranial and some postcranial remains of a single individual described here as a new genus and species. These specimens are the first fossil lorisids known from outside East Africa, and include the only recovered postcranial remains from slow-moving arboreal lorisines. The findings indicate that significant tracts of forests in the Siwalik environmental mosaic may have been utilized by hominoid primates, notably *Ramapithecus*.

Modern lorisids (the galagos, bushbabies, pottos and lorises) occur today in Asia, from forested India eastwards, and in Africa. Two genera of slow-moving lorises occur in Asia, and about four genera in Africa, two of which are slow movers and two others leapers. The slow movers (or lorisines) and the leapers (or galagines) can be distinguished by dental and especially postcranial morphology[3]. Until recently, the fossil record

0028-0836/81/070585-03$01.00

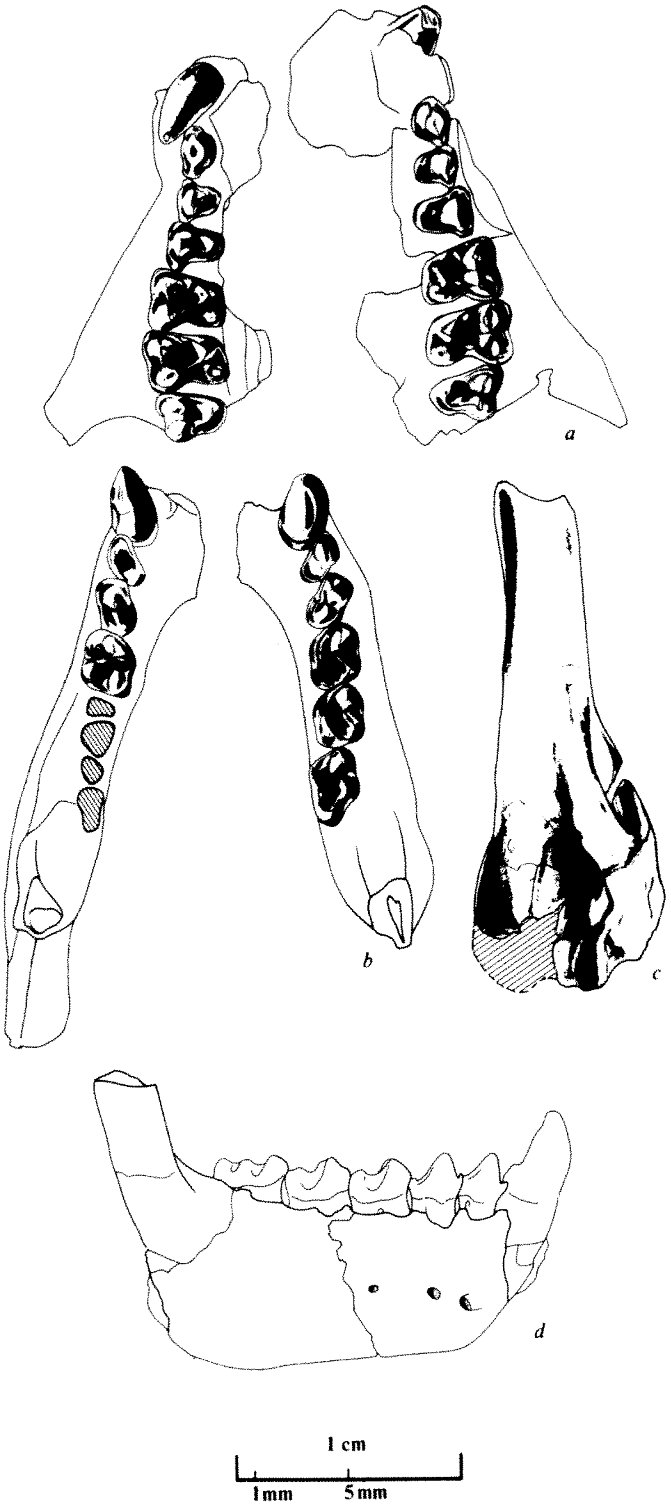

Fig. 1 *Nycticeboides simpsoni*, new genus and species, from the Pakistan Siwaliks: *a*, upper dentition; *b*, lower dentition; *c*, distal humerus; *d*, right dentary in labial view.

of lorisids was confined to East Africa, in deposits of Miocene–Pleistocene age[3–5]. The oldest Asian find, a fragmentary tooth (YGSP 8094), is from YGSP locality 259 in the Siwaliks[6,7]. (*Indraloris* was described as a Siwalik lorisid by Lewis. Known specimens, including many that are undescribed, do not have any features that place them in the Lorisidae; rather, Gingerich and Sahni have placed *Indraloris* with *Sivaladapis* in the Adapidae.) Two other localities (YGSP localities 450 and 182A) have produced isolated lorisid teeth. Hominoid primates, including *Ramapithecus*, and tree shrews are found at or near these three localities[8]. The ages of the localities are between 10 and 8 Myr ago, based on associated faunal and palaeomagnetic data[1,2]. Tree shrews now live in forested regions of Asia from India eastwards.

The youngest Siwalik locality to produce a lorisid is YGSP locality 363. It occurs higher in the section than the last occurrence of hominoids, and therefore is probably younger than 8 Myr (ref. 2). The lorisid remains are from one individual, and no other taxa have been recovered from the locality. It represents a new genus and species *Nycticeboides simpsoni.* This taxon (Fig. 1) is known only from the holotype (YGSP 8091), which includes most of the dentition with the exception of upper incisors and parts of the anterior lower dentition. Some skull fragments and a few postcranial fragments, mostly unprepared, are also represented. *N. simpsoni* is a lorisid because it has a tooth comb[9], the mandibular symphysis is not fused, the morphology of the cheek teeth is similar to and the dental formula apparently the same as those of other lorisids (see ref. 10). It is referred to the subfamily Lorisinae because the premolars are relatively simple, the postorbital bar is strong, the mandible heavy, and the humerus has a weak ectepicondylar flange. The generic name reflects similarities to *Nycticebus* and the species is named after Dr George Gaylord Simpson.

For the present, the diagnosis is the same for both genus and species because this is a monotypic taxon. The dentary is heavy with a vertical, robust ascending ramus where it joins the horizontal ramus. The cheek teeth are relatively simple, without strong cingula. The premolars are not strongly molariform. Among living lorises, *Nycticeboides* is most similar to *Nycticebus* in the shape of the base of the ascending ramus and in the morphology of P_3 and P_4. However, *Nycticeboides* has weaker labial cingula on molars and stronger styles on P^3 and P^4. It is similar in size to *Nycticebus coucang pygmaeus* (Table 1; for measurements of *N. coucang pygmaeus*, see ref. 11). *Nycticeboides* is distinct from *Loris* in having a narrow P^4, more rounded cusps on the cheek teeth and better developed cingula on P_3 and P_4. The hypocone on upper molars is stronger and the P^3 more molariform in *Nycticeboides* than *Perodicticus. Arctocebus* and *Mioeuoticus* are distinct from *Nycticeboides* in having

more nearly square molars with stronger cingula and, in the case of *Arctocebus*, stronger ridges connecting cusps on molars.

The way in which lorisines and galagines move is reflected in the shape of their humeri. Galagines are vertical clingers and leapers with a fairly broad habitat tolerance[3]. Lorisines are slow-moving arboreal quadrupeds, limited in distribution to fairly dense jungle. The humerus of *Nycticeboides* is more similar to that of modern, slow-moving lorises in having a weak ectepicondylar flange (Fig. 1*c*). In addition, the relative weakness of the lesser tuberosity and the buttress for insertion of the *teres major* resembles lorisines rather than galagines, although this conclusion is less secure because of the lateral distortion of the proximal end of the humerus. However, this distortion would tend to exaggerate similarities with galagos rather than lorises.

N. simpsoni represents a lorisine of modern grade in locomotor adaptation. As a lorisine, it suggests the presence of tracts of jungle large enough to support the existence of slow-moving arboreal quadrupeds in that area of South Asia up to at least 7 Myr ago, regardless of what other components of environmental mosaic were available. If the older lorisids of the Siwaliks were similarly adapted, and if the joint occurrence of taxa at a fossil locality reflects community composition, then the hominoid *Ramapithecus* was probably at least an occasional visitor to forest tracts inhabited by lorises and tree shrews.

Immediate phytochrome action in inducting α-galactosidase in lettuce seeds

David W. M. Leung & J. Derek Bewley

Department of Biology, University of Calgary, Calgary, Alberta,
Canada T2N 1N4

The light-induced breaking of dormancy of Grand Rapids lettuce seeds imbibed in darkness at 25 °C is a classical phytochrome-controlled phenomenon[1]. Although it has been shown that irradiation of seeds 1–2 h after the start of imbibition produces the active form of phytochrome (Pfr) which acts rapidly after its formation[2,3], the completion of germination (observed as radicle protrusion) is only evident several hours later. Clearly, then, radicle emergence is temporally removed from the rapid (and presumably primary) action of phytochrome. Very little is known about the processes set in motion by Pfr that lead to the completion of germination. Here we report that red light-induced stimulation of α-galactosidase (EC 3.2.1.22) activity occurs substantially before germination is completed, and show that the action of phytochrome in promoting an increase in the activity of this enzyme is very rapid.

Table 1 Effects of brief red-light irradiation on α-galactosidase activity and germination in lettuce seeds

Treatment	Time after start of imbibition (h)	Enzyme activity (units × 10^4 per seed)	% Germination
Dry seeds	0	12.6	—
Irradiated seeds	5	18.5	0
	12	18.6	10 (100)
Dark-imbibed seeds	5	12.5	0
	12	12.8	2 (8)

Batches of 25–50 lettuce seeds (*Lactuca sativa* cv. Grand Rapids, Ferry Morse Seed Co.) were allowed to imbibe in darkness at 25 °C. After 1.5 h from the start of imbibition some seeds were induced to germinate by 3 min of red light obtained from two 20-W Cool White fluorescent tubes filtered through a Ruby Red Cinemoid filter transmitting maximally at 660 nm (ref. 7). After 5 or 12 h triplicate batches of seeds were collected, their germination scored and they were ground in 0.05 M potassium phosphate buffer (*p*H 6.85) to obtain a crude homogenate. After clearing at 12,000*g* for 20 min at 2 °C the extract was assayed for α-galactosidase activity. The assay mixture contained 0.1 ml each of McIlvaine buffer, *p*H 5.2, *p*-nitrophenyl α-D-galactopyranoside (10^{-3} M) (Sigma) dissolved in buffer, and properly diluted enzyme extract. After incubation at 30 °C for 5–15 min, 1.0 ml of cold Na_2CO_3 (10^{-1} M) was added to terminate the enzyme reaction. Control experiments consisted of adding substrate at the end of the incubation. Enzyme activity was measured by a change in absorbance at 400 nm due to enzymatic release of *p*-nitrophenol. The molar extinction coefficient for *p*-nitrophenol was taken as 1.84×10^4 and 1 unit of enzyme activity is defined as that which brings about the release of 1 μmol of *p*-nitrophenol per min in the above conditions of assay. Variability in enzyme activity between triplicate samples of seeds was within ±0.4 units × 10^4 seed. Values in parentheses show the percentage of germination 24 h after the start of imbibition.

Table 1 shows that lettuce seeds in darkness at 25 °C (that is, dormant seeds) maintain the same level of α-galactosidase as dry seeds, whereas red light promotes both germination and an appreciable increase in α-galactosidase activity. This increase occurs within 5 h of the start of imbibition and within 3.5 h of irradiation. This is well before radicle emergence, which is noticeable some 5–7 h later. Enzyme activity and germination are induced by a 2-min exposure to red light, but not by shorter irradiations (Table 2). The promotional effect of 2-min red light on germination is abolished if far-red light is then applied immediately, but the red light-induced increase in α-galactosidase activity is unaffected.

Table 2 Effects of a single brief far-red light irradiation on enzyme activity in lettuce seeds treated with a single brief red-light irradiation or in seeds imbibed in darkness

Irradiation treatment	% Germination	Enzyme activity (units × 10^4 per seed)
None	8	12.4
Red 1 min	8	12.5
Red 2 min	84	16.8
Red 2 min + far-red 8 min or 20 min	4	16.9
Far-red 8 min or 20 min	5	12.4

Seeds were imbibed in darkness, or given red light 1.5 h after imbibition. One batch of red light-treated seeds was irradiated immediately with either 8 min or 20 min far-red light, along with one batch of dark-imbibed seeds. Seeds were collected at 24 h for counting the percentage germinated, and at 5 h for α-galactosidase determination, as described in Table 1 legend. Far-red irradiation was obtained from a 100-W tungsten filament lamp filtered through Ilford filters 608 and 806 transmitting between 700 and 1,000 nm.

In view of the rapid action of Pfr in lettuce seeds[2,3], and the observation that there is a rapid escape from photoreversibility

0028-0836/81/070587-02$01.00

Table 3 Effects of intermittent brief red light irradiations separated by periods of brief far-red light irradiations or by periods of darkness on lettuce seed germination and levels of α-galactosidase activity

Irradiation treatment	Total equivalent time of red light irradiation (min)	% Germination	Enzyme activity (units × 10^4 per seed)
a, Red 5 s + far-red 25 s, 24×	2	4	16.6
Red 5 s + darkness 25 s, 24×	2	84	16.9
b, Red 2 s + far-red 8 s), 60×	2	4	12.8
Red 2 s + darkness 8 s, 60×	2	80	16.7
c, Red 2 s + far-red 8 s, 30×	1	4	12.6
Red 2 s + darkness 8 s, 30×	1	8	12.6

Seeds imbibed in darkness for 1.5 h were irradiated as shown, and each irradiation sequence was repeated the number of times indicated. The timing of irradiations was within ±0.5 s.

(of the order of seconds) of the potentiation of flowering in *Pharbitis nil*[4], and perhaps of other phenomena[5], we studied the possibility that a rapid Pfr action is also involved in the promotion of α-galactosidase activity. The 2-min promotional period of red light was therefore applied as repeated 2- or 5-s pulses, with intervening longer periods of far-red light or darkness. Two-second pulses of red light (cumulative to 2 min) with intervening dark periods resulted in a high percentage of germination and full promotion of enzyme activity (Table 3*b*). With intervening periods of far-red light, however, both germination and enzyme activity were suppressed. Five-second pulses of red light with intervening dark periods also resulted in high germination and full enzyme activity, but the latter was not suppressed by intervening periods of far-red light (Table 3*a*). If the cumulative time of red light pulses was less than 2 min there was no promotion of germination or enzyme activity (Table 3*c*).

Several important points arise from these experiments. First, red light promotes an increase in the activity of a hydrolytic enzyme, α-galactosidase, before the completion of germination. Second, the promotional effects of red light on germination and α-galactosidase activity are cumulative, provided that the critical total exposure time of 2 min is achieved. However, far-red light can inhibit germination at times when enzyme activity is unaffected, indicating two distinct phytochrome-controlled reactions. Third, the effects of Pfr on the induction of enzyme activity are very rapid, and exposure to red light for only 5 s precludes the possibility that far-red light has any subsequent inhibitory effects, even though it still has a strong negative effect on germination. Thus, the consequences of Pfr action for between 2 and 5 s are irreversible as far as the induction of α-galactosidase activity is concerned. Such a rapid action of phytochrome on enzyme induction is unknown elsewhere, and is unlikely to be explained in terms of direct gene activation[6]. It is not known whether α-galactosidase is involved in dormancy-breaking in lettuce seeds, and its role may be associated with the early mobilization of raffinose reserves[7,8]. Certainly, its presence in the lettuce seed cannot be correlated directly with germination because it can be induced in conditions that retain seeds in their dormant state (Tables 2, 3). Although the role of Pfr in inducing α-galactosidase is only transient, the enzyme itself does not arise until some 3 h after irradiation, indicating that certain events set in motion by Pfr must take time to be completed.

True morphology of the Azotobacteraceae—filterable bacteria

J. Gonzalez Lopez* & G. R. Vela

Department of Biological Sciences, North Texas State University,
Denton, Texas 76203

The history of bacteriology up to the 1950s contains many references to filterable forms of bacteria but misconceptions regarding the nature of filterability eventually made the entire phenomenon an unresolvable paradox[1–4]. Although the existence of filterable azotobacter has often been reported[5–9], so much doubt in these results has been expressed[10,11] that now Bergey[12] does not even mention filterability. In 1965 we reported the resistance of soil azotobacter to γ rays and concluded that the possibility of a very small *Azotobacter* form could not be dismissed[13] and as a result of studies on survival in soil, we suggested the possible existence in soil of a still undiscovered phase of the *Azotobacter* cyst[14]. We report here the discovery of these small, soil azotobacter and provide evidence to support this claim.

The Azotobacteraceae are usually cultured in chemically defined, nitrogen-free media with an organic compound as a source of carbon. Growing cells are large, rod-shaped and pleomorphic but as cultures age, morphological variability

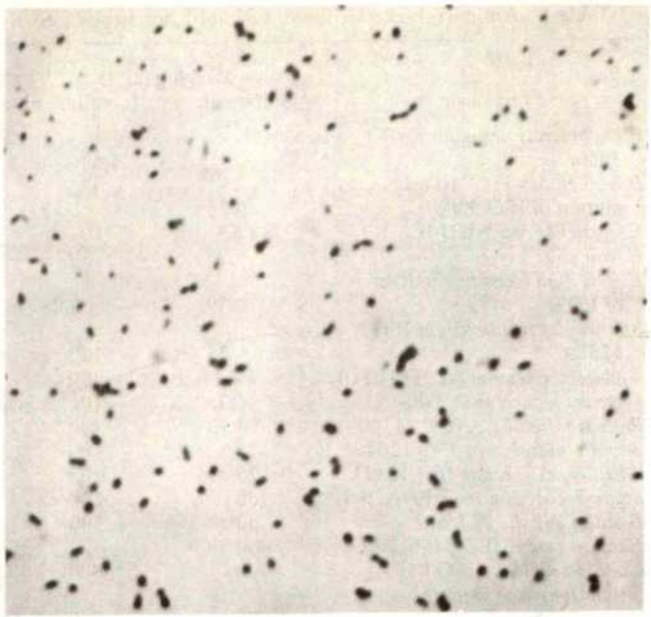

Fig. 2 Isolated germinal cellulae of *A. vinelandii* 12837 grown in dialysed soil media to a final population of $\sim 1 \times 10^7$ cellulae ml^{-1} and filtered through 0.45-μm membrane filters. ×2,220.

increases and cell debris appears, sometimes including regular, spherical or slightly elongated particles ~0.3 μm in diameter, similar to those previously reported[5,6,15]. When 10–30-day-old cultures of azotobacter were filtered through 0.45-μm membrane filters and plated on Burk's nitrogen-free medium[16], ~10% of filtrates yielded some viable cells (unpublished data). The use of different media including soil plates and different soil extract formulations did not significantly alter these findings.

In this study we pulverized dry garden soil, sifted it through gauze and placed it in dialysis tubing in 10-g amounts. Tubes were tied at both ends, placed in 50 ml of distilled water in 250-ml flasks and heated in the autoclave at 121 °C for 15 min. These conditions were established as being adequate for sterilization by the addition of sterile tryptic soy broth to selected flasks and incubation of these as sterility controls in all tests. The dialysis bags filled with soil were left in the flask cultures as a continuing source of nutrients. This growth medium remained clear, soil particles did not spill out of dialysis bags (see Fig. 1) and, when bacteria grew, they did not penetrate the bag. The dialysed soil medium was inoculated with stock cultures of *Azotobacter vinelandii* A.T.C.C. 12837 and incubated on a rotary shaker at 28 °C. After 24 h, normal cells of *A. vinelandii* were present and also many cell-like particles ~0.3 μm in diameter (Fig. 1) which passed through 0.45-μm membrane filters. Control cultures in Burk's nitrogen-free media contained only the large cells.

Filtrates were subcultured in dialysed soil medium and at each transfer, both the normal and filterable cells grew to large populations. The integrity of each filter was ascertained by adding to each azotobacter suspension a few drops of a culture of *Serratia marcescens* and plating a few drops of the unfiltered mixture and a few drops of the filtrate on tryptic soy agar. If *S. marcescens* failed to grow from the unfiltered cell mixture or if it grew from the filtrate, the test was disregarded on the grounds that it was not proved that the filter could retain bacteria. Subculture from the dialysed soil medium (unfiltered) transferred to Burk's medium yielded large cells only.

Filterable particles able to generate large cells of azotobacter have previously been called corpuscles, gondida, gonidingia, microgonidia, chromidia, autospores and endospores. We suggest that they be called germinal cellulae to describe their nature more clearly.

A. vinelandii germinal cellulae were separated from large cells by filtering 72-h-old dialysed soil cultures and centrifuging the filtrate (20,000*g*, 10 min). Microscopy revealed no large cells but many germinal cellulae (Fig. 2). When inoculated into dialysed soil media, germinal cellulae gave rise to the large cells of *A. vinelandii* (confirmed by physiological/biochemical tests) and more cellulae, but if the latter were isolated and placed in Burk's medium, they did not grow, indicating that germinal cellulae can grow only in dialysed soil medium. We suggest that the germinal cellulae are formed in large numbers ($\sim 1 \times 10^7$ per ml of culture) (Fig. 3) in the soil medium but only rarely or not at all in Burk's medium. Our experiments were repeated 32 times, with identical results. The relationship between the large cells of *A. vinelandii* 12837 and the germinal cellulae was obvious when cultures in dialysed soil media were examined at 4-h intervals for several days: germinal cellulae grew, divided and gave rise to large cells which in turn gave rise to new populations of germinal cellulae. These growth cycles were determined in two ways. First, the ratio of large cells to germinal cellulae was determined directly on stained smears of culture samples. Second, filtered and unfiltered culture samples were plated on a solid medium comprising 20 g of agar per litre of soil medium (dialysis bag discarded). The difference between the two viable cell counts represented the ratio of filterable germinal cellulae to large cells. There was good agreement in results obtained by the two methods.

Other Azotobacteraceae which gave filterable cellulae when cultured in the dialysed soil medium were: *A. vinelandii* OP, S4, S5 and S6, *Azotobacter chroococcum* AC16, *Azomonas macrocytogenes* 8702, *A. macrocytogenes* s. TM, *A. macrocytogenes* ZAM and *Beijerinckia indica*.

Our observations suggest that, in an environment similar to their natural habitat, the soil azotobacter exist as filterable cells ~0.3 μm in diameter, whereas the large cells usually seen in chemically defined laboratory cultures seem to be only a transient reproductive form.

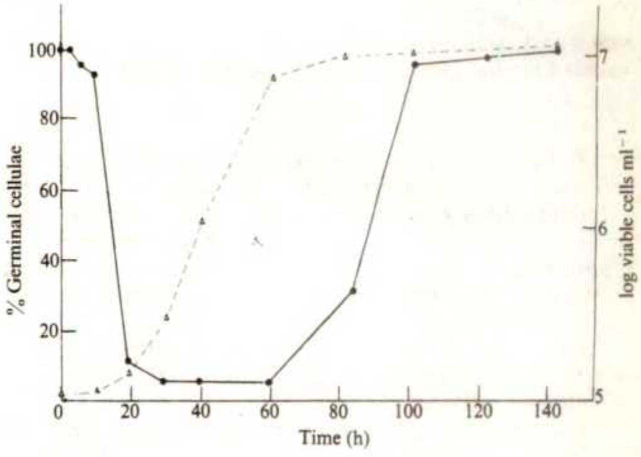

Fig. 3 *A. vinelandii* 12837 grown in dialysed soil medium at 28 °C. The continuous line shows the ratio of germinal cellulae to large cells. The broken line indicates total viable cell count on dialysed soil agar plates.

To test this hypothesis we collected 72 different soils and suspended 1-g portions of each in 10 ml of distilled water. These were agitated for 5 min, *S. marcescens* added and then filtered through 0.45-μm membrane filters. All samples inoculated into flasks of dialysed soil medium yielded azotobacter cultures whereas those inoculated into Burk's nitrogen-free medium did not. When the former cultures, containing large cells and germinal cellulae, were subcultured on Burk's nitrogen-free agar plates, they gave colonies of *A. chroococcum* and *A. vinelandii*, usually obtained from Texas soils. Replicates of this experiment always produced the same results. Three water samples from a sewage treatment plant also yielded filterable azotobacter when cultured in dialysed soil but not in nitrogen-free media. We therefore believe that azotobacter in their natural habitat exist as small, filterable cellulae incapable of growing in chemically defined, nitrogen-free media but able to grow in dialysed soil media as described here.

Sulfazecin and isosulfazecin, novel β-lactam antibiotics of bacterial origin

A. Imada, K. Kitano, K. Kintaka, M. Muroi & M. Asai

Microbiological Research Laboratories, Central Research Division, Takeda Chemical Industries Ltd, Yodogawa-ku, Osaka 532, Japan

In the long history of screening for antibiotics, fungi[1,2] and actinomycetes[3–8,19] have been the only producers of β-lactam antibiotics although several phytopathogenic bacteria have been reported to produce toxins with a β-lactam structure[9,10]. We report here the first evidence that novel monocyclic β-lactam antibiotics, sulfazecin and isosulfazecin, are produced by new species of *Pseudomonas*.

Screening for β-lactam antibiotics was carried out using a selective and sensitive method involving *Pseudomonas aeruginosa* PsC^{ss} (ref. 11) and *Escherichia coli* PG8 (lacking chromosomal β-lactamase and penicillin-binding protein (PBP) 1B), which are hypersensitive to β-lactam antibiotics. Several bacterial strains producing β-lactam antibiotics were isolated from soil, mostly using agar plates acidified to *p*H 4.5. The selected bacteria were categorized into two taxonomic groups: one group represented by strain G-6302 which produced sulfazecin and another by strain SB-72310 which produced isosulfazecin. Bacterial strains of both groups are polar-flagellated Gram-negative rods; the flagellation of strain G-6302 was monotrichous and that of strain SB-72310 multitrichous. Both strains were strictly aerobic, catalase-positive, oxidase-negative, poly-β-hydroxybutyric acid-accumulating and had no nutritional requirements. Arginine dihydrolase was found in strain SB-72310, but not in strain G-6302. The G+C content of the DNA was 64 mol% in strain G–6302 and 70 mol% in strain SB-72310. On the basis of these characteristics, both strains were regarded as members of the genus *Pseudomonas*. None of the defined species of *Pseudomonas* described by Bergey[12] exhibits these particular combinations of characters. In addition, both strains were unique in their *p*H dependence for growth. They grew well at *p*H 4.0 whereas those species of *Pseudomonas* described[12] do not. However, growth was poor at alkaline *p*H: strains G-6302 and SB-72310 failed to grow at *p*H >8.3 and >8.9, respectively. We designated strain G-6302 *Pseudomonas acidophila*, and strain SB-72310 *Pseudomonas mesoacidophila*, to denote their acidophilic and moderately acidophilic properties, respectively.

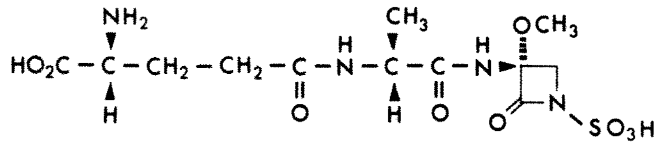

Fig. 1 Structure of sulfazecin.

Table 1 Antimicrobial activities of sulfazecin and isosulfazecin

Organism	MIC (μg ml^{-1}) Sulfazecin	Isosulfazecin
Pseudomonas aeruginosa IFO 3080	800	1,600
P. aeruginosa PsC^{ss} (sensitive mutant of IFO 3080)	0.78	0.78
Escherichia coli NIHJ JC2	12.5	100
E. coli LD2*	6.25	50
E. coli PG8 (sensitive mutant of LD2)	0.39	0.78
Salmonella typhimurium IFO 12529	6.25	100
Klebsiella pneumoniae IFO 3318	25	400
Proteus vulgaris IFO 3988	6.25	100
Proteus mirabilis ATCC 21100	3.13	100
Serratia marcescens IFO 12648	25	100
Alcaligenes faecalis IFO 13111	25	25
Staphylococcus aureus FDA 209P	200	200
Bacillus subtilis PCI 219	50	100
Bacillus cereus IFO 3466	800	400
Candida albicans IFO 0583	>800	>800
Saccharomyces cerevisiae IFO 0209	>800	>800
Aspergillus niger IFO 4066	>800	>800
Penicillium chrysogenum IFO 4626	>800	>800

Minimum inhibitory concentrations (MICs) were assayed by the twofold agar dilution method using nutrient agar containing 20 μg ml^{-1} *meso*-diaminopimelic acid. *meso*-Diaminopimelic acid was added to suffice the requirements of *E. coli* LD2 and PG8. When fungi and yeasts were the test organisms, glucose was supplemented at 1%.

* See ref. 14.

On cultivation of these bacteria in nutrient broth containing appropriate carbon and sulphur sources, antibacterial substances accumulated extracellularly. The active principles were thought to be β-lactam antibiotics because they selectively inhibited β-lactam antibiotic-hypersensitive mutants, *P. aeruginosa* PsC^{ss} and *E. coli* PG8, induced the formation of spheroplasts, and were slightly inactivated by β-lactamases.

To prepare the active principles, fermentation was carried out at 28 °C for 3 days with aeration and agitation in a 2,000-litre fermenter containing 1,200 l of medium (3% glycerol, 0.1% glucose, 0.1% sodium thiosulfate and 0.5% each of peptone, meat extract and NaCl). The antibiotics accumulated were purified using activated charcoal, anion-exchange resin and Sephadex, followed by crystallization as free acid from aqueous methanol.

The physicochemical properties of sulfazecin, produced by strain G-6302, are as follows: $C_{12}H_{20}N_4O_9S$, m.p. 168–170 °C,

0028-0836/81/070590-02$01.00

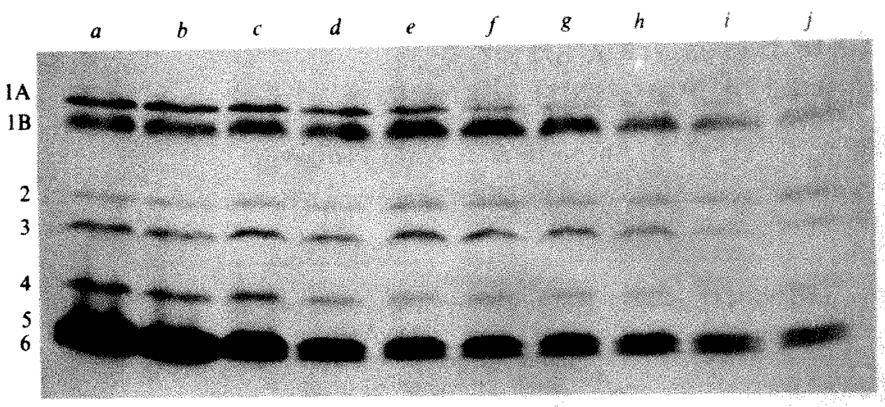

Fig. 2 Competition of sulfazecin for ^{14}C-benzylpenicillin binding to envelopes of *E. coli* LD2. The assay of PBP was performed as described[14], with slight modifications. Cell envelopes (12 mg protein ml^{-1}) of *E. coli* LD2 were preincubated with water or increasing concentrations of sulfazecin. The PBPs remaining accessible were labelled with a saturating concentration of ^{14}C-benzylpenicillin (48.2 μCi ml^{-1}, 53 mCi $mmol^{-1}$). PBPs were detected by exposure of the dried gel to an X-ray film for 26 days at −80 °C. The final concentrations of sulfazecin were (μg ml^{-1}): *a*, 0; *b*, 0.33; *c*, 0.82; *d*, 2.05; *e*, 5.12; *f*, 12.8; *g*, 32; *h*, 80; *i*, 200; and *j*, 500. Concentrations required to inhibit ^{14}C-benzylpenicillin binding by 50%, calculated from the fluorogram, were (μg ml^{-1}): PBP 1A, 11; PBP 1B, 270; PBP 2, >500; PBP 3, 150; PBP 4, 2.2; and PBP 5/6, 1.6.

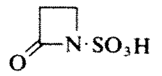
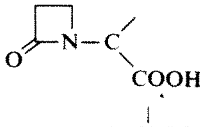
$[\alpha]_D^{25} + 82°$ ($C = 0.44$, H_2O), no UV absorption maximum above 210 nm, characteristic IR absorption bands at 1,775 cm^{-1} (β-lactam carbonyl), 1,660 cm^{-1} (amide carbonyl), 1,240 cm^{-1}, 1,040 cm^{-1} and 630 cm^{-1} (SO_3). The antibiotic gave a positive ninhydrin reaction. It was readily soluble in water but sparingly soluble in organic solvents except for polar aprotic solvents, for example, dimethylformamide. On hydrolysis with 6 M HCl at 110 °C, D-glutamic acid and D-alanine were obtained, and on mild hydrolysis with 1M HCl at 37 °C, γ-D-glutamyl-D-alanylamide and 2-oxo-3-sulphoaminopropionic acid were isolated. X-ray analysis of the intact antibiotic established the structure of sulfazecin[13]. The absolute configuration of sulfazecin was determined as 3(*R*)-3-γ-D-glutamyl-D-alanylamino-3-methoxyazetidin-2-one-1-sulphonic acid (Fig. 1) from the evidence that D-amino acids were obtained by acid hydrolysis. The name 'sulfazecin' was given to denote the fact that sulphonic acid is structurally unique in its direct link to the nitrogen atom of azetidin-2-one. Other characteristic features are a methoxyl group attached to C-3 of the azetidine ring, which is responsible for the resistance to β-lactamases (unpublished observation) and a dipeptide comprising the side chain.

The physicochemical and chromatographic properties of isosulfazecin, produced by strain SB-72310, were almost identical to those of sulfazecin, except for the optical rotation: $[\alpha]_D^{25}$ of isosulfazecin was +4.5° ($C = 1.01$, H_2O). Amino acids formed by acid hydrolysis were D-glutamic acid and L-alanine. This indicates that isosulfazecin is an epimeric isomer of sulfazecin; D-alanine in sulfazecin is replaced by L-alanine in isosulfazecin.

Sulfazecin and isosulfazecin are thus proved to be novel monocyclic β-lactam antibiotics of unique structure. The



moiety is essential to the antibacterial activity (unpublished observation) and its presence definitely differentiates sulfazecin and isosulfazecin from all known β-lactam antibiotics, including monocyclic nocardicin, that possess the



moiety. The sulphamate group (—N·SO_3H) is rarely found in nature. To our knowledge, heparin and the related *N*-sulphonated glycans are the only naturally occurring products ever found to contain this group. Although certain monocyclic β-lactams with antimetabolite activity[9,10,19] are structurally related to sulfazecin, they have neither sulphonate group at N-1 nor aminogroup at C-3 of the azetidine ring.

The antimicrobial activities of sulfazecin and isosulfazecin are shown in Table 1. Sulfazecin was active against Gram-negative bacteria and weakly active against Gram-positive bacteria. Isosulfazecin was weakly active against both Gram-negative and Gram-positive bacteria. The mutants hypersensitive to β-lactam antibiotics were extremely sensitive to both antibiotics whereas fungi and yeasts were insensitive.

Sulfazecin was also effective *in vivo*. The ED_{50} of sulfazecin administered subcutaneously was 6.98 mg per kg against mice infected intraperitoneally with *E. coli*. The toxicities of both antibiotics were extremely low; no mice died after intravenous injection of sulfazecin at 10 g per kg.

The action of sulfazecin was further examined using *E. coli* as the test organism. It was bacteriostatic at 6.25 and 12.5 μg ml^{-1}, and bactericidal at 25 μg ml^{-1} or more. The cells became filamentous when exposed to the bacteriostatic concentrations and changed to ghosts when exposed to bactericidal concentrations. Sulfazecin competed in the binding of ^{14}C-benzylpenicillin to PBPs (Fig. 2); affinity was high for PBPs 4 and 5/6 and low for 1, 2 and 3 (see Fig. 2 legend). It is interesting that the monocyclic sulfazecin, although structurally different from the bicyclic penicillins and cephalosporins, showed affinity for PBPs. The fact that the affinity for PBPs 1, 2 and 3, the apparent lethal targets in *E. coli*[15-18], was not high enough to explain the antibacterial activity suggests some alternative mode of action for sulfazecin. Further studies on the mechanism of action of sulfazecin could lead to a better understanding of the mechanism of action of β-lactam antibiotics or of biosynthesis of peptidoglycan.

We thank Dr E. Ohmura for his interest and encouragement in this work.

Mite faeces are a major source of house dust allergens

E. R. Tovey, M. D. Chapman & T. A. E. Platts-Mills*

Division of Immunology, Clinical Research Centre, Watford Road,
Harrow, Middlesex HA1 3UJ, UK

The association between house dust allergy and asthma has long been recognized, and it has been demonstrated that a major allergen in house dust is related to the presence of mites of the genus *Dermatophagoides*[1]. Using extracts of mite culture for skin testing, as many as 10% of the population and up to 90% of allergic asthmatics give positive immediate reactions[2]. Although mites may occasionally become airborne during bed-making[3], it has also been demonstrated that they 'secrete or excrete' some allergen[1]. Recently, we have shown that up to three-quarters of the serum IgE antibodies to mites are directed against a major allergen—antigen P_1 (molecular weight 24,000)[4]. Using a radioimmunoassay it is possible to measure the concentration of this glycoprotein in both dust samples and mite cultures. These measurements, which are reported here, show that more than 95% of the allergen accumulating in mite cultures is associated with faecal particles.

When the components of mite culture were separated, whole mites, cuticles and mite faeces contained antigen P_1 but eggs contained very little (Table 1). The number of faecal particles in cultures seemed to be very high from direct microscopy. Using a mean value of 20 faeces per day, we estimated that after 1 month faeces would account for >95% of the antigen P_1 in cultures. These particles are roughly spherical and have a relatively smooth surface (Fig. 1). They are 10–40 μm in diameter and their size is directly proportional to the size of the mites producing them, which vary in length from 170 to 350 μm ($r = 0.91$, $P < 0.001$). The antigen P_1 content of faecal particles, mite culture or house dust elutes very rapidly in saline, whereas the allergen content of live mites is only very slowly eluted (Fig. 2).

Table 1 Quantity of antigen P_1 in mite culture components

	Culture components	ng antigen P_1 per 100 components	% Of total antigen P_1
Mites	Female	185	0.6
	Male	105	
	Immature	75	
Cuticles		29	0.4
Eggs		0.4	–
Faeces	Mixed size (22 ± 6 μm)	12	99
	Large (31 ± 8 μm)	17	
	Small (17 ± 4 μm)	3	

Antigen P_1 content of separated components of mite culture. Live mites (Bencard) were grown on Oxoid liver powder for 1 week at 24 °C and 75% relative humidity. Individual components were separated, homogenized, extracted with borate-buffered saline and assayed for P_1 content by double antibody inhibition radioimmunoassay[4]. The contribution of the components to the total P_1 content of culture is based on a mean lifetime for a mite of 3 months involving three changes of cuticle and an estimated rate of defaecation of 20 faeces per day. Two methods were used to measure the rate of defaecation. When the mean time for the passage of coloured food through the mite gut (5 h) was multiplied by the mean number of faeces produced by an isolated fully fed mite (mean 8 faeces, range 6–11), a rate of 40 faeces per mite per day was obtained. Alternatively, counting the number of faeces produced by mites fed on large washed lumps of culture media after 6 days in culture gave a mean rate of defaecation of only 6 faeces per day in these suboptimal conditions. Faecal sizes are means ± s.d.

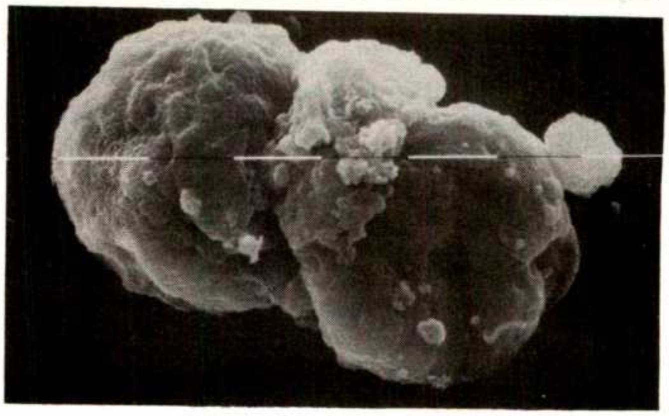

Fig. 1 Electron scanning micrograph of two mite faecal balls. Mite faeces range from 10 to 40 μm in diameter with a mean of 22 ± 6 μm s.d. For a similar species it has been reported[9] that the faeces are produced by compacting three to five foodballs covered in a peritrophic membrane. Scale bar, 10 μm.

As most particles deposited on the nasal mucosa are swallowed within 10 min, rapid elution of proteins is probably essential for allergenic activity[5]. It is not uncommon for house dust samples to contain over 1,000 mites and 30 μg of antigen P_1 per gramme. Based on the values in Table 1, such samples probably contain over 250,000 faeces per gramme of dust. Our further studies have shown that antigen P_1 is only present in the air of houses during domestic activity and this allergen is associated with particles >10 μm in diameter[6]. In general, particles of this size would be deposited on the mucosa of the nose and oropharynx and only occasional particles would be expected to enter the lungs[7]. In keeping with this, most dust-allergic asthmatic patients are not aware of a direct relationship between dust exposure and the onset of bronchospasm. The concentration of allergen in mite faeces is very high, approximately 10 mg antigen P_1 per ml, assuming 0.1 ng of allergen in a sphere of 20 μm diameter. These particles, whose physical properties are similar to those of pollen grains, would seem to be a very effective way of carrying proteins to the nasal mucosa. In addition, the few particles entering the lungs would be expected to cause localized inflammatory responses because of the high concentrations of allergen[8]. Our results suggest that the relationship between dust mite allergy and bronchial asthma is best

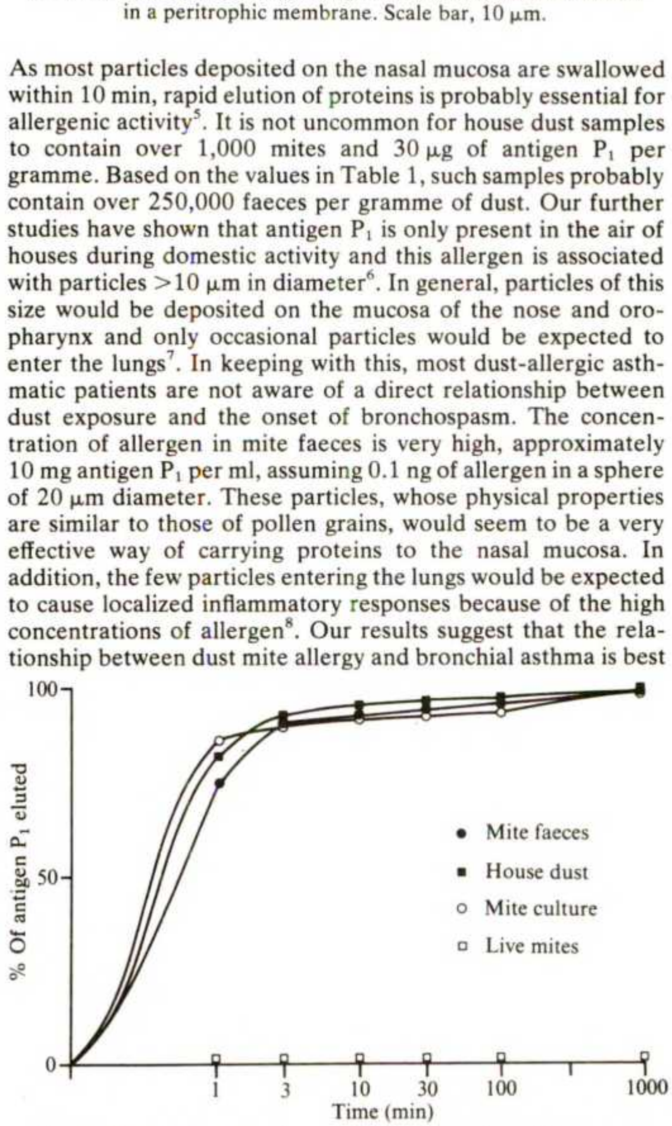

Fig. 2 The elution of antigen P_1 from faeces, live mites, house dust and culture material. Mite faeces or live mites mounted on Cellotape (1 × 5 mm) were contained in a section of capillary tubing and eluted with saline using a peristaltic pump (25 μl min^{-1}). At the end of the elution period 11 of the 60 mites were still mobile and none was observed to defaecate during the elution. Samples of house dust and culture material were repeatedly eluted in filter funnels under vacuum (30 ml, Scinterglass 4, 5 μm pore size). With house dust, culture material and faeces, the quantities of P_1 are expressed as a % of the total eluting over 16 h. With live mites the quantity of P_1 is expressed as a percentage of the quantity obtained by homogenizing the mites.

Diphtheria toxin (DT) is a single polypeptide chain of molecular weight 62,000 with two disulphide bridges[1]. Immunization against diphtheria rests on the stimulation of antibodies against detoxified toxin which also combine with the native toxin. Because the antibodies differ functionally from each other, however, only some of them are able to neutralize toxicity[2–4]. We have therefore set out to synthesize part of the amino acid sequence of the toxin whose function as a stimulator of antibodies might be less ambiguous, and have chosen the loop of 14 amino acids subtended by the disulphide bridge nearer the NH_2 terminus of the molecule (Fig. 1). There is reason to think that this loop may be involved in the toxicity and immunological specificity of the molecule[1,5]. We report here our finding that the tetradecapeptide (residues 188–201), when linked covalently with two different carriers, will elicit in guinea pigs antibodies which not only bind specifically with the toxin but neutralize its dermonecrotic and lethal effects. To our knowledge these results constitute the first example of successful active immunization against a lethal bacterial toxin using a synthetic antigen.

Fig. 1 Sequence of the diphtheria toxin loop within the NH_2-terminal disulphide bridge as inferred from the complete sequence of fragment A (ref. 14) and the data reported for the NH_2-terminal stretch of fragment B (ref. 15).

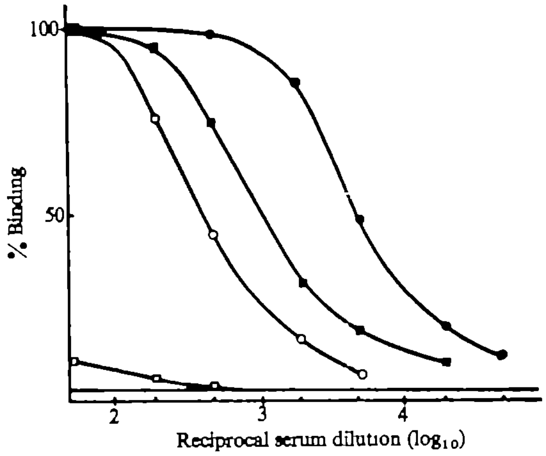

Fig. 2 Binding of radiolabelled diphtheria toxin by anti-SDP and anti-STDP sera. DT was iodinated by the chloramine-T technique. Using appropriate dilutions, 98% of the radioactivity present in the antigenic preparation after labelling was bound by a hyperimmune anti-DT horse serum (gift from M. Mazert). Serial dilutions of anti-toxoid and anti-peptide sera were tested for their capacity to bind ^{125}I-labelled diphtheria toxin. Percentages were obtained in each tube from the formula: c.p.m. found in precipitate ×100/total c.p.m. ●, Anti-toxoid serum corresponding to the pooled sera of group 1 (see Table 1 legend); ■, anti-toxoid serum (pooled sera of group 2); ○, anti-SDP (pooled sera of group 5); □, anti-STDP serum (highest responder of group 6); —, normal rabbit serum.

The sequences 194–201, 192–201 (synthetic decapeptide SDP), 190–201, 188–201 (synthetic tetradecapeptide STDP) and 186–201 were prepared by solid-phase methodology using *m*-nitrobenzhydrylamine resin and benzhydrylamine resin. The first polymer retains the peptide after hydrogen fluoride (HF) treatment to remove protecting groups of the side chains of the amino acids[6]. Despite certain gaps, such as those caused by destruction of cysteine, the elongation of the sequences can be followed by amino acid analysis performed on the peptidyl resin[7]. With the second polymer, HF treatment cleaves peptides in their carboxylamide terminal form[8]. Peptides were purified by gel filtration and proved homogeneous by TLC. Their amino acid composition agreed with that obtained theoretically. Details of the different syntheses will be published elsewhere.

Octa-, deca- (SDP), dodeca-, tetradeca- (STDP) and hexadecapeptides linked to the *m*-nitrobenzyhydrylamine resin were tested for their ability to combine with anti-DT antibodies. These sera were raised in horses and rabbits, and the immunoglobulins purified and labelled with ^{125}I. Whereas SDP seemed to be the smallest structure capable of binding to antibodies, this property increased strikingly with the hexadecapeptide. Because free SDP and STDP were the only compounds available in sufficient amounts, they were covalently linked to bovine serum albumin (BSA) by their amino groups using glutaraldehyde and administered to guinea pigs in conditions described in Table 1 legend. The resulting sera were tested by passive haemagglutination. Using the SDP–BSA conjugate, only one out of five animals gave detectable response, whereas all but one of the animals challenged with STDP–BSA gave significant

Table 1 Individual response of guinea pigs to toxoid, SDP and STDP

Immunization	Passive haemagglutination titre Mean	Individual values
Toxoid:		
(1) 3 Lf+FCA	13.8	14 - 14 - 14 - 14 - 13
(2) 3 Lf	11.8	12 - 12 - 12 - 12 - 11
(3) 0.3 Lf	3.8	7 - 4 - 4 - 2 - 2
(4) 0.03 Lf	0.2	1 - 0 - 0 - 0 - 0
(5) SDP–BSA	1.6	8 - 0 - 0 - 0 - 0
(6) STDP–BSA	4.67	10 - 5 - 5 - 4 - 4 - 0

[1] Groups of guinea pigs were injected in each hind footpad with 0.1 ml of the immunizing preparations and 30 days later re-injected in the same conditions. Data represent the $\log_2$ of passive haemagglutination titres of individual sera collected 3 weeks after the second injection, using sheep red blood cells coated with diphtheria toxin by glutaraldehyde in experimental conditions to be described elsewhere. Groups are the following: guinea pigs immunized by diphtheria formalin-toxoid: (1) 3 Lf in FCA; (2) 3 Lf in saline; (3) 0.3 Lf in saline; (4) 0.03 Lf in saline; guinea pigs immunized by peptide conjugates: (5) SDP–BSA 1 mg in FCA; (6) STDP–BSA 1 mg in FCA. 1 Lf = 2.5 μg protein; 1 MLD = 66 ng protein; 1 MRD = 0.1 ng protein.

0028-0836/81/070593-02$01 00

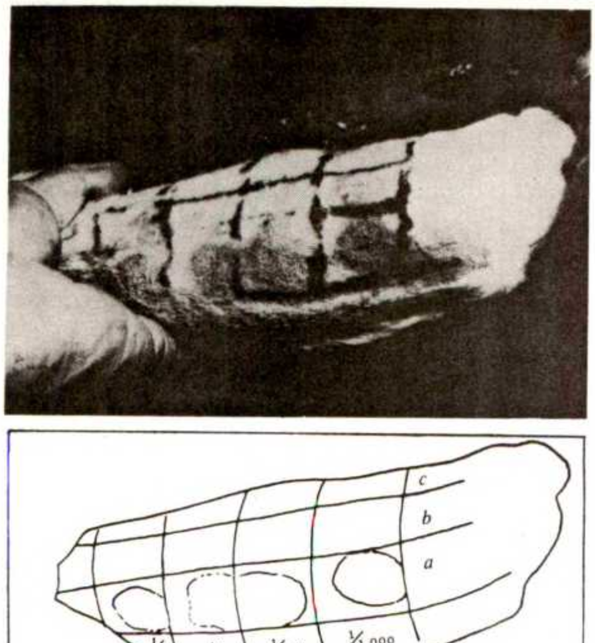

Fig. 3 Sera were diluted 2-, 10-, 100- and 1,000-fold in phosphate-buffered saline. They were mixed (1 : 1 v/v) with a 1,000 MRD ml^{-1} dilution of DT in calf serum. After incubation for 20 min at room temperature, 0.2 ml was injected intradermally in guinea pigs. *a*, Normal guinea pig serum; *b*, anti-STDP serum highest responder of group 6; *c*, anti-toxoid serum (pooled sera of group 2). Whereas positive dermonecrotic responses were observed with normal serum (*a*), responses were uniformly negative at all dilutions of *b* and *c* sera tested.

levels of antibodies. The titre ($\log_2$) of these pooled sera was 7.67 whereas pooled sera of guinea pigs immunized with 0.3 Lf of toxoid gave a titre of 5.15. (However, the latter preparation, unlike the former, was not injected with Freund's adjuvant.) No haemagglutination was observed with undiluted STDP antisera incubated with uncoated erythrocytes as controls. Radioimmunoassay gave results in agreement with those of the passive haemagglutination test (Fig. 2). Highly purified diphtheria toxin used in the present study was 90% in the 'nicked' form as evidenced by SDS-polyacrylamide gel electrophoresis. Previous incubation with DT inhibited the haemagglutinating and binding activities of anti-peptide sera.

More interesting is the finding that anti-STDP antibodies neutralized the dermonecrotic activity of DT. Necrosis caused by 100 minimum reactive doses (MRD), and both necrosis and erythema caused by 10 MRD, were totally inhibited by 10-fold diluted pooled sera (not shown) or even by a 1,000-fold dilution of the serum with the highest binding and agglutinating titres (Fig. 3*b*). Preliminary experiments on protection against lethal activity of the toxin showed that 0.5 ml of the latter anti-STDP serum protected guinea pigs against two minimal lethal doses (MLD).

Further experiments, which will be detailed elsewhere, also indicate that DT binding antibodies could be obtained by STDP coupled to the synthetic branched copolymer multi-poly-DL-alanyl-poly-L-lysine (abbreviated A--L). Moreover, DT binding antibodies have also been obtained by administering a synthetic adjuvant MurNAc-L-Ala-D-isoGln(MDP)[9,10] with either STDP–BSA or STDP–A--L in saline instead of Freund's complete adjuvant (FCA). Previous investigators used synthetic antigens containing a portion of sequences of various proteins to study the structural parameters of immunogenicity[11,12]. A pioneering example is that of lysozyme, for which the loop region between Cys 64 and Cys 80 was prepared synthetically and when coupled to poly-DL-alanyl-poly-L-lys, successfully elicited antibodies reactive with native lysozyme[13]. The work developed here could provide useful tools for a closer investigation of the molecular interaction between DT and its fragments with sensitive cells. Antibodies directed against a limited portion of the toxin molecule such as the NH_2-terminal loop should present a reduced heterogeneity. In addition, as the antigen was obtained by chemical synthesis, the biological activity of analogues can also be investigated.

These experiments and those in progress suggest the possibility of developing a completely synthetic antidiphtheria vaccine. Such a model could be extended to other infective microorganisms whenever their immunogenic structures can be defined and synthesized.

We thank A. M. Pappenheimer Jr and W. B. Vernon for the useful discussions which initiated the present work, Dr Raulais for the amino acid analysis and Ms Bassot for technical assistance. This work has been supported by INSERM grant CRL. 80.10.02.

Thyroid growth-blocking antibodies in primary myxoedema

H. A. Drexhage*†, G. F. Bottazzo*, L. Bitensky†, J. Chayen† & D. Doniach*

Adult primary myxoedema is usually due to an autoimmune thyroiditis characterized by progressive shrinking of the thyroid gland, loss of epithelium, dense infiltration by sensitized lymphocytes and plasma cells with final replacement of the gland by a fibrous scar[1]. Antibodies directed against thyroglobulin (TgHA) and microsomal antibodies (McHA), detectable years before the onset of hormonal failure, and cell-mediated immune mechanisms contribute to the pathogenesis[2]. When 90% of the gland is destroyed, the secretion of thyroid hormones (T_3/T_4) falls below normal needs and pituitary thyrotrophs react by producing over 100 times the normal amount of thyroid-stimulating hormone (TSH)[3] which should normally lead to regrowth of the gland as happens in goitrous Hashimoto thyroiditis[4]. The inability of the thyroid in primary myxoedema to respond to the trophic action of TSH suggested that blocking antibodies exist in this disease which compete with TSH for its receptors[5,6]. The trophic effect of TSH can be assayed *in vitro* by measuring DNA-synthesis by Feulgen cytophotometry[7]; elevated pentose-shunt oxidative activity correlates with DNA synthesis[8]. Here we report that immunoglobulins from patients with adult, primary myxoedema block the trophic effect of TSH, as assessed by this *in vitro* system. This is in marked contrast to the growth stimulation induced by immunoglobulins from patients with thyrotoxic Graves' disease with prominent goitres[7].

0028-0836/81/070594-03$01.00

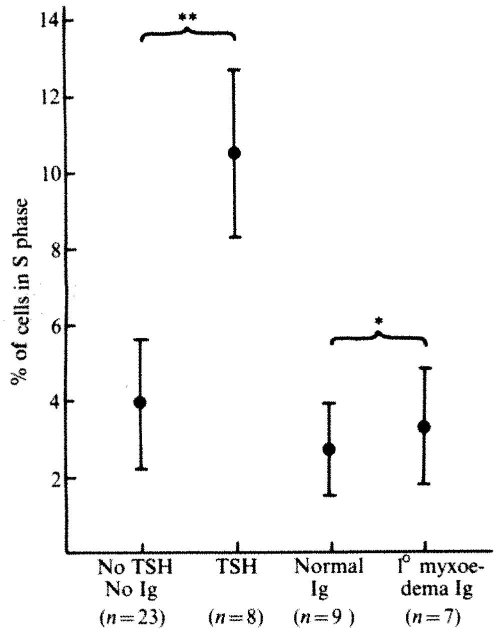

Fig. 1 DNA synthesis in thyroid explants measured by Feulgen densitometry. Guinea pig thyroid segments were exposed for 5 h to TSH, to immunoglobulin (Ig) of normal subjects, to immunoglobulin from primary myxoedema patients, or were cultured without any of these. **, $P<0.01$; *, not significant.

Immunoglobulins were prepared by ammonium sulphate precipitation from the sera of 10 middle-aged female patients with primary myxoedema. All had impalpable glands and, despite exaggerated TSH responses to exogenous thyrotropin-releasing hormone, they produced negligible secretion of thyroid hormones. Nine had detectable thyroid antibodies (McHA titre 10^2–160^2; TgHA titre 20–>5,000). Most of these patients were on replacement therapy with thyroxine at the time of testing. As controls, immunoglobulins from subjects with the following conditions were studied: (1) Goitrous Hashimoto thyroiditis (three female patients), with even higher titres of thyroid antibodies (McHA 80^2–$1{,}250^2$; TgHA 20–>5,000). (2) Graves' thyrotoxicosis, two patients with goitres of estimated weight >60 g and two without thyroid enlargement (<30 g). Thyroid growth-stimulating antibodies had been demonstrated in the former, but not the latter pair[7]. (3) A case of congenital hypothyroidism (athyreotic cretinism) due to failure of the descent of the thyroid gland, in which the myxoedema, in the presence of high levels of TSH, is due to lack of functioning thyroid tissue. In addition, normal immunoglobulin from a pool of 20 healthy subjects and from two members of the laboratory staff were tested.

For each comparative study, five segments of a single guinea pig thyroid gland were maintained at 37 °C for 5 h in Trowell's non-proliferative organ culture[9] with TSH (0.3 μU ml^{-1}; MRC Research Standard A) in the medium. The sixth segment was maintained without TSH. For four of the segments exposed to TSH, the medium also contained a standard concentration of the relevant immunoglobulin preparation (125 μg ml^{-1}) for the entire 5-h period. This immunoglobulin concentration was shown to be optimal for stimulating DNA synthesis[7]. At the end of the 5-h period, the segments were chilled, sectioned and reacted either by the Feulgen reaction[7] or for glucose 6-phosphate dehydrogenase (G6PD) activity with neotetrazolium chloride as the final hydrogen acceptor and phenazine methosulphate as intermediary carrier[10]. The reaction products were measured in 50–100 individual thyroid-follicle cells by scanning and integrating microdensitometry[11] (×100 oil immersion objective; scanning spot 0.2-μm diameter in the plane of the section; λ 550 nm for the former and 585 nm for the latter). By Feulgen cytophotometry, DNA synthesis (S phase and G_2) was defined by the presence of at least 2.8 times the C value, so excluding the normal distribution of cells in G_0 or G_1 close to the $2C$ value. ($2C$ is the normal diploid DNA content of resting cells, which doubles to $4C$ before mitosis.)

TSH stimulated DNA synthesis, with 10.3% (±2.5% s.d.) of the cells in S phase compared with 3.9% (±1.7%) in segments maintained in the absence of TSH (Fig. 1). An equivalent stimulation of G6PD activity (145% ± 15% of control value) by TSH was also recorded. The immunoglobulin derived from each of the 10 patients with primary myxoedema blocked the stimulation of DNA synthesis, depressing the number of cells found in S phase down to 28–88% of the value found with TSH alone (Fig. 2). The immunoglobulin from seven of these patients also diminished the TSH-induced stimulation of G6PD activity. In contrast, the immunoglobulin from most of the other cases enhanced the stimulatory effects of TSH in both tests, or at least did not counteract the stimulation induced by TSH. The only exception was obtained with the immunoglobulin from a patient with Graves' thyrotoxicosis but with no palpable goitre, which showed slight blocking of DNA synthesis but no blockade of the G6PD stimulation.

In general, the results of the nucleic acid cytophotometry correlated well with those of the G6PD assay ($r=0.59$; $P<0.01$). However, with a few of the immunoglobulins tested, discrepancies were found between the two tests, probably due to the involvement of the pentose shunt in metabolic functions other than growth[12].

When they were tested alone in this system, none of the immunoglobulins that blocked the effect of TSH affected DNA synthesis (Fig. 1). There was no correlation between the growth-blocking potentiality of any given immunoglobulin preparation and the titre of microsomal antibody ($r=0.22$; $P>0.05$).

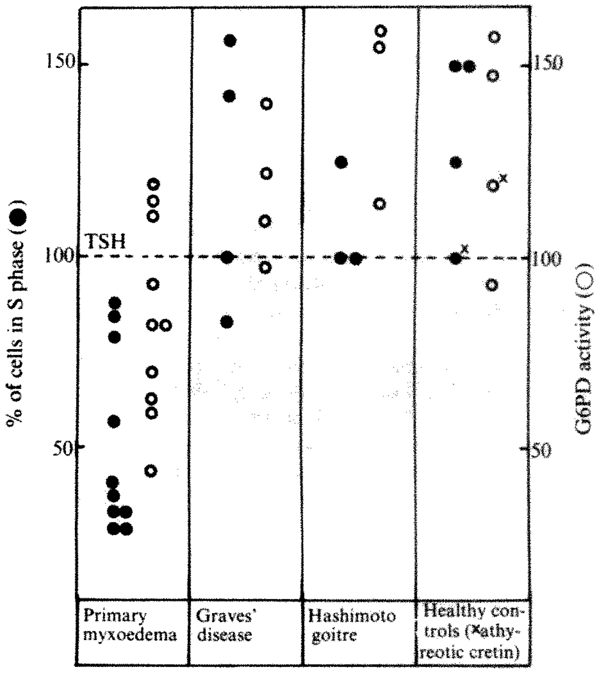

Fig. 2 Effect of the addition of immunoglobulins from several groups of patients on TSH-stimulated DNA synthesis and pentose-shunt activity in guinea pig thyroid tissue. The DNA synthesis (% of cells in S phase, ●) and the pentose-shunt activity (G6PD activity per 100 cells, ○) are expressed as a percentage of the results found with TSH alone within each assay (dashed line = TSH level = 100 per cent).

In support of our results, it has been suggested that spontaneous hypothyroidism preceding or following an attack of thyrotoxicosis could be due to blocking antibodies[5,13]. Moreover, previous studies have shown that occasionally immunoglobulins from patients with Graves' disease[14] and from two patients with myxoedema[6,15] had blocking potential in that they inhibited the stimulation of adenylate cyclase induced by TSH or by other Graves' immunoglobulins. Adenylate cyclase-inhibiting antibodies have recently been reported to cross the placental barrier, giving rise to transient hypothyroidism in the newborn[15]. A similar phenomenon explains the report[16] in which a mother treated for primary myxoedema gave birth to several babies with temporary hypothyroidism. Antibodies able to block TSH-induced stimulation of growth rather than TSH-induced hormone synthesis were less likely to be responsible for the transient hypothyroidism in this family because the thyroid gland was of normal size in one baby who died[16]. However, antibodies influencing thyroid growth are likely to cross the placenta as transient neonatal thyrotoxicosis is often accompanied by goitre[17]. Blocking antibodies have been demonstrated in other autoimmune conditions—acetylcholine receptor antibodies in myasthenia gravis[18], insulin receptor antibodies in insulin-resistant diabetes with acanthosis nigricans[19] and parathyroid hormone receptor antibodies in some cases of renal failure[20]. Our study indicates the existence of antibodies which block the trophic effects of TSH. These antibodies are probably distinct from those that block TSH-induced hormone synthesis through the adenylate cyclase pathway. Thyroid atrophy, together with loss of function, might be caused by the simultaneous presence of these two types of blocking antibodies in primary myxoedema.

We thank Ms L. Hammond for technical assistance and Miss P. C. Lamb for typing the manuscript. H.A.D. was supported by a Royal Society Exchange Fellowship. Work was also supported by a MRC grant.

Block of acetylcholine-activated ion channels by an uncharged local anaesthetic

D. C. Ogden, S. A. Siegelbaum & D. Colquhoun

Department of Pharmacology, University College London,
Gower Street, London WC1E 6BT, UK

It is now thought that amine local anaesthetic compounds (procaine, lignocaine and related molecules) depress electrical activity in nerve and muscle cells by binding to sites within ion channels and blocking current flow. Such mechanisms have been proposed to account for the effects of these local anaesthetics on both the voltage-dependent sodium current[1-3] and the postsynaptic acetylcholine (ACh)-activated ionic current[4-7]. Recently, strong evidence for block of ion channels by cationic drug molecules has been obtained by recording current from single ACh-activated channels in the presence of permanently charged quaternary derivatives of lignocaine[8]. Most amine local anaesthetic compounds are, however, weak bases, present in both charged and uncharged forms at physiological *p*H, and some question remains as to whether a charged group is essential for blockade of ion channels[1,9,10]. To resolve this question, we studied the action of the uncharged local anaesthetic benzocaine (ethyl-4-aminobenzoate) on postsynaptic ACh- activated endplate current and extrajunctional single channel current of frog muscle. We report here evidence that strongly suggests that benzocaine blocks ACh-activated ion channels.

The effect of benzocaine on spontaneous miniature endplate currents (m.e.p.cs) is illustrated in Fig. 1. In the absence of drug (Fig. 1*a*), the m.e.p.c. decays along a single exponential time course with time constant τ_c. After addition of 300 μM benzocaine (Fig. 1*b*), the peak m.e.p.c. amplitude is reduced and the current decline becomes biphasic, with an initial rapid component followed by a slow tail. This decay can be fitted well by the sum of two exponential components, with time constants faster, τ_f, and slower, τ_s, than the control time constant, τ_c. On increasing the drug concentration to 500 μM (Fig. 1*c*), there is a further reduction in peak m.e.p.c. amplitude, the fast exponential current component becomes more rapid, and the slow decay phase becomes slower.

Analysis of ACh-induced current fluctuations in the absence and presence of benzocaine reveals similar effects on endplate current kinetics to those seen with m.e.p.cs (Fig. 2). Figure 2*a* shows a power spectrum of ACh-induced current noise in the absence of benzocaine. The spectrum is well described by a single lorentzian function, characterized by a cut-off frequency, f_c, which is related to the time constant, τ, by $\tau = (2\pi f_c)^{-1}$. In 200 μM benzocaine, Fig. 2*b*, the power spectrum is composed of two lorentzian components with cut-off frequencies corresponding to fast and slow time constants, τ_f and τ_s. These time constants from noise analysis are in good agreement with the time constants obtained from fitting m.e.p.c. decay (within experimental error, when normalized to the same temperature).

The results with benzocaine resemble the reported action of charged local anaesthetic compounds[4-6,11] and suggest, as an initial hypothesis, the following mechanism for open channel block[12]:

$$R \underset{\alpha}{\overset{\beta'}{\rightleftharpoons}} R^* \underset{k_b}{\overset{x_B k_f}{\rightleftharpoons}} R^*B \qquad (1)$$

Here R is a closed (non-conducting) channel, R* an open (conducting) channel, and R*B an open channel blocked by drug molecule B (also non-conducting). The reaction $R \rightleftharpoons R^*$ represents the normal channel gating mechanism (when agonist binding is fast)[13]; β' is the effective, agonist concentration-dependent, rate constant for channel opening and α is the rate constant for shutting (approximately equal to τ_c^{-1}). The reaction $R^* \rightleftharpoons R^*B$ represents block of an open channel (with blocker concentration x_B), with association rate constant k_f, and dissociation rate constant, k_b. This mechanism predicts that, in the presence of drug, endplate current decays as the sum of rapid and slow exponential components whose rates are, respectively, speeded and slowed with increasing drug concentration. This agrees with our m.e.p.c. and noise results.

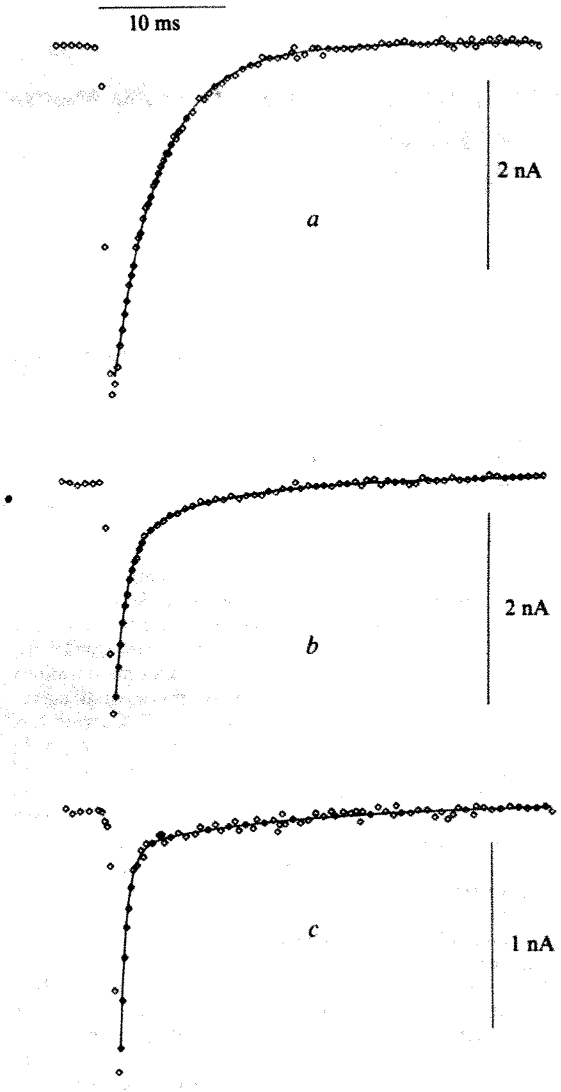

Fig. 1 Concentration dependence of the effect of benzocaine on m.e.p.c. Records are digitized, computer-averaged m.e.p.cs (8–14 individual currents) from a cutaneus pectoris muscle fibre (*Rana temporaria*) voltage-clamped to −100 mV. *a*, In the absence of benzocaine, averaged m.e.p.c. rises rapidly (within <1 ms) to a peak inward value. Current decay is fitted by a single exponential function (continuous curve) with time constant, $\tau_c = 3.8$ ms. *b*, Averaged m.e.p.c. recorded 15 min after switching to solution containing 300 μM benzocaine. Current decay fitted by the sum of two exponential components (continuous curve) with time constants, τ_f and τ_s, of 1.0 and 7.6 ms. Relative amplitude of the fast to slow exponential component at the time of the peak m.e.p.c., $I_0(f)/I_0(s) = 3.0$. *c*, Averaged m.e.p.c. obtained after 17 min in the presence of 500 μM benzocaine. The parameters of the two fitted exponentials (continuous curve) are: $\tau_f = 0.7$ ms, $\tau_s = 11.6$ ms and $I_0(f)/I_0(s) = 6.8$. Note change in current scale from *a* and *b* to *c*. Inward current is plotted in a downward direction. Muscle fibre was voltage-clamped with a conventional two-microelectrode technique and applied current measured via a KCl-agar bridge and Ag/AgCl bath electrode, connected to a virtual ground amplifier. Currents were filtered between 0.02 Hz (high pass) to 1.3 kHz (low pass). All curves were fitted using a least squares procedure. The Ringer solution contained 116.5 mM NaCl, 2.5 mM KCl, 1.5 mM $CaCl_2$ plus 50 nM tetrodotoxin and was buffered to *p*H 7.4 with 5 mM HEPES. Temperature, 11.5 °C. Muscle fibre 42-1.

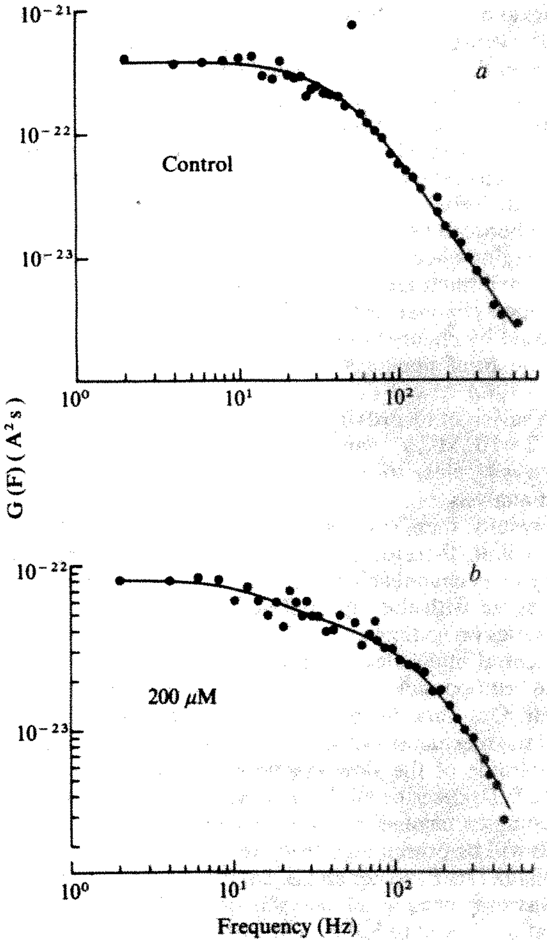

Fig. 2 Analysis of the effect of benzocaine on agonist-induced current fluctuations. *a*, Spectral density of current noise produced by bath-application of 4 μM ACh. The continuous line is a fitted single lorentzian curve; cut-off frequency, $f_c = 42.5$ Hz. *b*, Spectral density of current noise produced by application of 5 μM ACh in the presence of 200 μM benzocaine. The continuous curve is the sum of two lorentzian functions with cut-off frequencies of 17.0 and 154.8 Hz. Relative amplitude of zero frequency asymptotes of fast to slow components is 0.9. Spectra were obtained by subtracting the average of 50–60 individual spectra in the absence of agonist from the average of 50–60 spectra in the presence of agonist. Membrane potential, −70 mV; temperature, 8 °C. Cutaneus pectoris muscle fibre 43-2. Cholinesterase not inhibited.

A second prediction of the model is that the sum of the fast and slow decay rate constants (reciprocal time constants) minus the control rate constant should depend linearly on drug concentration according to; $\tau_f^{-1} + \tau_s^{-1} - \tau_c^{-1} = x_B k_f + k_b$. This prediction is tested in Fig. 3, using data pooled from many separate noise experiments. The data are fitted well by a linear relation, in agreement with the channel block model. The slope of the line yields a value for k_f of $2.6 \pm 0.3 \times 10^6\ M^{-1}\ s^{-1}$ and the intercept yields a value of $296 \pm 124\ s^{-1}$ (mean ± s.d.) for the unblocking rate, k_b. The apparent equilibrium constant, K^*, for the binding of benzocaine to its blocking site is then given by: $K^* = k_b/k_f = 114$ μM. These values are within a factor of five of those obtained for ACh channel block (at −70 mV) by charged and partially ionized drugs, QX-222 (ref. 8) and procaine[4]. The rates for channel block by benzocaine obtained in this way do not depend noticeably on membrane potential.

Recordings of single ion channel currents, illustrated in Fig. 4, show more directly the behaviour expected if benzocaine blocks open ion channels. In the absence of benzocaine (Fig. 4*a*) single channel openings give rise to rectangular current pulses. The channels stay open for a random lifetime that is exponentially distributed. In the presence of 200 μM benzocaine (Fig. 4*b*) the rectangular control current pulses are divided into bursts of rapid activity. When viewed on the expanded time scale of Fig. 4*c*, these bursts can be seen to be composed of a series of rapid openings and closings. No evidence for two channel populations, one with average open time shorter and one with average open time longer than control, was detected. Two population models have been invoked to explain biphasic m.e.p.cs in the presence of the lipophilic drug hexanol[14].

The single channel records in the presence of benzocaine are similar in appearance to records obtained in the presence of QX-222 by Neher and Steinbach[8]. Following their analysis, the bursts in benzocaine can be interpreted in the following manner: a burst begins when a channel opens ($R \rightarrow R^*$), the rapid switchings within a burst are caused by drug blocking and unblocking of the open channel ($R^* \longleftrightarrow R^*B$), until, finally, the burst is terminated by channel closure ($R^* \rightarrow R$). The mean open time, τ_0, of the brief openings within a burst should be given by $\tau_0 = (\alpha + x_B k_f)^{-1}$, and the mean blocked time, τ_b, is equal to $1/k_b$. Analysis of records like those in Fig. 4 gives values for k_f of $1.8 \pm 0.2 \times 10^6\ M^{-1}\ s^{-1}$ and for k_b of $270 \pm 20\ s^{-1}$ (mean ± s.e.m., $n = 4$), close to the rates obtained above from endplate current analysis.

Our results, then, suggest that benzocaine blocks open ACh channels and, therefore, that charge *per se* does not have a critical role in channel block by amine local anaesthetics. These results agree with the reported action of neutral amine local anaesthetics on sodium channels[1,9] and also with evidence that other neutral molecules, including the uncharged form of barbiturate compounds[12] and prednisolone[15], block endplate channels. Our data do show some deviations from the predictions of the mechanism specified in equation (1)[16]; in particular, the amplitude of the slow kinetic component is smaller than predicted. To describe all the observed effects of benzocaine, a more complex channel block mechanism must be postulated, and this will be presented elsewhere.

We thank Drs E. Neher and B. Sakmann for their advice. This work was supported by a fellowship of the Muscular Dystrophy Association (USA) to S.A.S. and by the MRC.

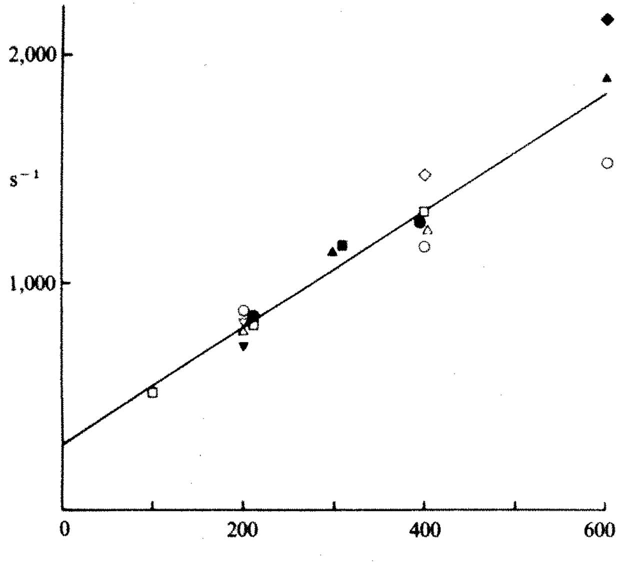

Fig. 3 Plot of $\tau_f^{-1} + \tau_s^{-1} - \tau_c^{-1}$ against benzocaine concentration. Data were obtained from noise analysis as described for Fig. 2. Each symbol represents a different experiment, all at −70 mV membrane potential. The line was fitted by the method of least squares. Temperature was between 6.5 and 10.5 °C, rates normalized to 8 °C using a Q_{10} for τ_f^{-1} of 1.7, a Q_{10} for τ_s^{-1} of 1.6 (D.C.O. and S.A.S., unpublished), and a Q_{10} for τ_c^{-1} of 2.7 (ref. 13).

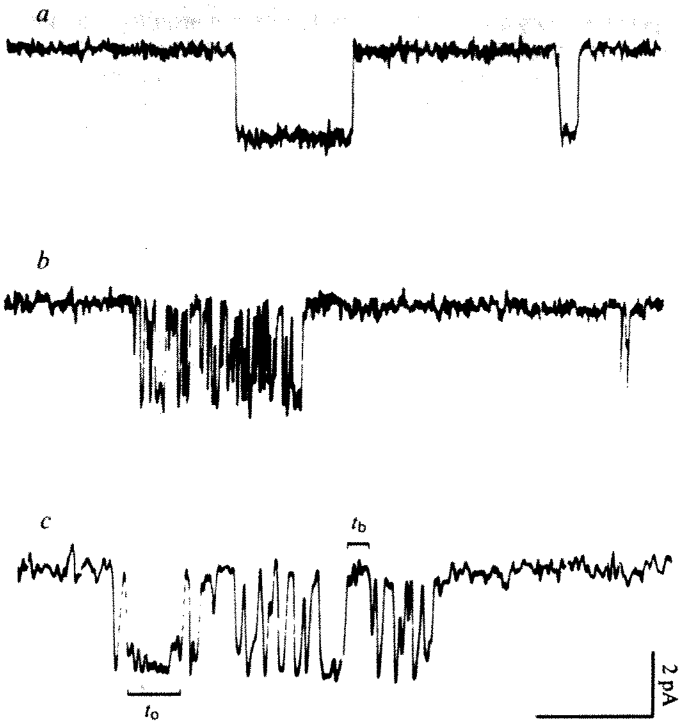

Fig. 4 Effects of benzocaine on single ACh channel currents, recorded with an extracellular patch pipette. *a*, Single channel current in the absence of benzocaine. The pipette contained Ringer solution plus 100 nM ACh. Mean channel open time, $\tau_0 = 19$ ms, was obtained by constructing a histogram of open time durations for many channel openings and fitting an exponential curve. Membrane potential, −110 mV; temperature 9 °C. Current low pass filtered at 400 Hz. Fibre 121-4. *b*, Single channel currents in the presence of 200 μM benzocaine (benzocaine in pipette as well as bath). Records were obtained from the same muscle as in *a*, but with a different fibre. Membrane potential, −130 mV; 100 nM ACh in pipette; temperature 9 °C. Current filtered at 460 Hz. Fibre 121-7. *c*, A burst in 200 μM benzocaine (from same run as *b*) at better time resolution. Current filtered at 800 Hz. The brackets indicate one open interval (t_0) and one blocked interval (t_b). Histograms of open and blocked times were well fitted by single exponentials, yielding a mean open time of 2.8 ms and a mean blocked time of 3.5 ms. Time calibration bar corresponds to 200 ms in panels *a*, *b* and 50 ms in panel *c*. Downward deflection indicates inward current. Recordings obtained from the extrajunctional membrane of 4–6-week denervated semitendinosus muscle fibres. Single channel currents were recorded using methods described by Neher *et al.*[17] and Neher[18]. Suction was applied to the pipette interior to increase the seal resistance between pipette and fibre membrane to values greater than $5 \times 10^8\ \Omega$ (see ref. 18).

Alterations in brain cholecystokinin receptors after fasting

A. Saito*†, J. A. Williams*† & I. D. Goldfine*†‡

Cholecystokinin (CCK) is the parent molecule of a family of polypeptide hormones, some of which are secreted from the small intestine after food ingestion and stimulate both exocrine secretion and gall bladder contraction[1–4]. CCK-like molecules have also been identified in the central and peripheral nervous systems[5–12]. The significance of CCK in the brain is unknown, but it could mediate satiety. The satiety produced by introduction of food into the intestine[13] can be mimicked by systemic injections of CCK and its analogues[14–17]—these hormones are also effective when injected into the hypothalamus[18] and the cerebral ventricle[19]. Straus and Yalow showed that brain CCK levels were reduced in the cerebral cortex of both genetically obese (*ob/ob*)[20] and normal mice after a 2–5-day fast[21]. However, Schneider[22] detected no such reduction in similar conditions and other studies have suggested a peripheral rather than central action on satiety[23,24]. Using CCK of high specific activity, specific CCK receptors have been measured both in pancreatic acini and in various brain regions[25–28]. We show here that fasting in mice significantly increases CCK binding due to an increased number of CCK receptors in the olfactory bulb and hypothalamus, but not in other brain regions. In contrast, insulin binding to its receptors was not altered by fasting. As the hypothalamus is known to regulate appetite[29,30], this finding supports the concept that CCK regulates satiety through interaction with this brain region.

Male white Swiss mice were either allowed to feed *ad libitum* or underwent a 42-h fast, but were allowed water. In fasted animals, body weight fell from 33.8±0.45 to 30.8±0.89 g ($n = 16$). Both fed and fasted animals were then rapidly decapitated, the brain removed, specific regions isolated and brain particles prepared[26]. Specific ^{125}I-BH-CCK (CCK conjugated to labelled Bolton-Hunter reagent) binding to receptors was then measured[26] (Table 1). In both fed and fasted rats, specific CCK binding varied in different regions of the brain. However, when fed and fasted animals were compared, a significant increase in binding was seen in the olfactory bulb and hypothalamus of fasted animals (Table 1). Although several other brain regions, including cerebral cortex, hippocampus, midbrain, caudate and hindbrain, tended to show an increase in binding in fasted animals, the changes were insignificant (Table 1).

Scatchard analyses of CCK binding were then carried out in the olfactory bulb and hypothalamus; the cerebral cortex was studied concurrently as a control. Fasting was accompanied by a significant increase in the CCK binding capacity of both the olfactory bulb and hypothalamus, but not the cerebral cortex (Fig. 1). Preliminary studies indicate that 48 h after refeeding of fasted mice, the number of CCK receptors returns to the value seen in fed mice. In all brain areas studied, the binding affinity (K_d) was ~1 nM, a value similar to that previously reported for rat cerebral cortex[26].

In contrast to changes in CCK binding, no difference in CCK degradation by brain particles was detected in any of the brain regions from fasted animals. As insulin is another polypeptide hormone that binds to specific receptors in various regions of the brain[31] and these receptors do not change in various metabolic states[32,33], we used insulin binding to its receptors as a control. No differences in insulin binding to its receptors in various brain regions, including hypothalamus and olfactory bulb, were detected between fed and fasted mice.

The study indicates that fasting increases the number of CCK receptors in specific regions of mouse brain. Our data and those in the literature therefore support the view that metabolic alterations may change not only brain CCK levels, but also CCK receptor concentrations. There is evidence in rats and other rodents that the hypothalamus mediates satiety[29,30]. Bilateral destruction of the ventromedial hypothalamus of rats results in an increase in both food intake and body weight[29,30]. Furthermore, in rats with lesions in the ventromedial hypothalamus, there is reduced suppression of feeding by caerulein (a CCK analogue)[18]. The increase in the number of receptors for CCK in the hypothalamus after fasting shown here suggests that alterations in these receptors may be important in hunger and satiety.

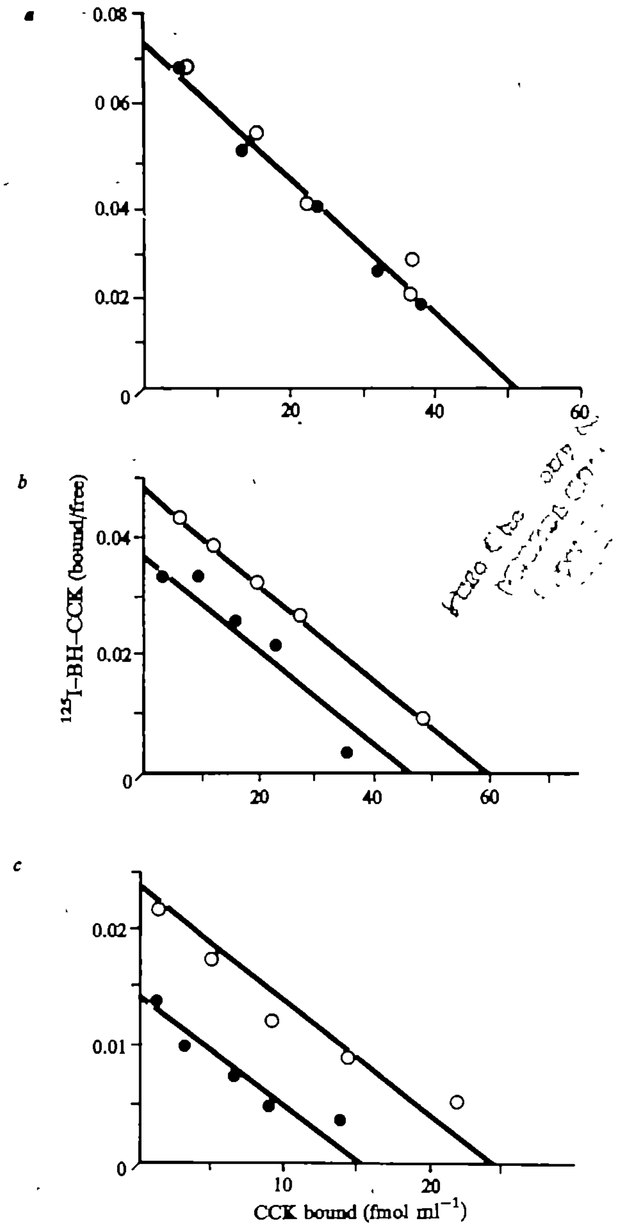

Fig. 1 Scatchard plots of specific ^{125}I-BH-CCK binding to cerebral cortex (*a*), olfactory lobe (*b*) and hypothalamus (*c*). ●, Fed; ○, fasted. Binding, expressed per mg protein per ml, was carried out as specified in Table 1. The ligand was added at 15 pM and unlabelled CCK was added in concentrations from 10 pM to 100 nM.

Table 1 Effect of fasting on CCK receptors in mouse brain

Region		Specific CCK binding (fmol per mg protein × 10^2)		% Increase in fasted
		Fed	Fasted	
Olfactory bulb	(11)	195 ± 22	285 ± 30	46+
Hypothalamus	(9)	99 ± 12	141 ± 13	42+
Hindbrain	(7)	70 ± 19	90 ± 11	29
Hippocampus	(7)	118 ± 10	139 ± 19	18
Cerebral cortex	(8)	397 ± 36	469 ± 41	18
Midbrain	(7)	103 ± 13	112 ± 11	9
Caudate	(7)	96 ± 8	92 ± 14	0

Mouse brain particles were prepared by a modification of the method of Uhl *et al.*[34]. Male Swiss mice (30–35 g), either fed or fasted for 42 h, were kept at 24 °C on a light–dark cycle changing at 9 a.m. and 9 p.m. The animals were decapitated between 9:30 and 11:00 a.m., the brain dissected on ice and the various regions homogenized in 10 volumes of 50 mM Tris-HCl (*p*H 7.4) at 4 °C by the use of a motor-driven Teflon-glass homogenizer[26]. The homogenate was centrifuged at 42,000*g* for 15 min at 4°C, resuspended in an equal volume of buffer and similarly recentrifuged. The pellet was then resuspended by homogenization in buffer containing 180 mM NaCl, 4.7 mM KCl, 5 mM $MgCl_2$, 1 mM EGTA, 1 mg ml^{-1} bacitracin, 5 mg ml^{-1} bovine serum albumin and 10 mM HEPES (*p*H 7.4)[26]. To measure binding, 50 pM ^{125}I-BH-CCK[25,26] was added in triplicate to plastic microcentrifuge tubes in a 300-µl final volume along with brain particles (final protein concentration 0.3–0.5 mg ml^{-1}) at 24 °C. After 120 min, the tubes were centrifuged at 10,000*g* in a Beckman 152 microcentrifuge at 24 °C. The pellets were rinsed with cold buffer, recentrifuged, the tips of the tubes cut off and radioactivity determined. Nonspecific binding was determined by adding unlabelled 10^{-6}M CCK_8 with the labelled hormone and this value was subtracted from total binding to yield specific binding[26]. Each value is the mean ± s.e. The number of experiments performed is given in parentheses. +, $P < 0.05$ (fasted compared with fed). In every experiment, CCK binding to its receptors in olfactory bulb and hypothalamus was greater in fasted than fed mice.

This research was supported by NIH grant AM26422 and the Elise Stern Haas Research Fund, Harold Brunn Institute, Mount Zion Hospital and Medical Center. We thank Dr H. Sankaran for preparing the ^{125}I-BH-CCK.

Vitamin D-dependent phosphorylation of an intestinal protein

P. W. Wilson & D. E. M. Lawson

Dunn Nutritional Laboratory, University of Cambridge and Medical Research Council, Milton Road, Cambridge CB4 1JX, UK

The complete pattern of response of target tissues to steroid hormones is still unclear although it seems that the initial biochemical events involve the transcriptional control of protein synthesis. A still outstanding problem concerns the role of these hormone-dependent proteins in the physiological response. Synthesis of several intestinal proteins is known to be stimulated by 1,25-dihydroxyvitamin D (1,25-$(OH)_2D$)[1]; at least one, calcium-binding protein (CaBP) by a transcriptional event[2]. Steroid hormones also stimulate protein phosphorylation[3] and we show here that 1,25-$(OH)_2D$ acting *in vivo* stimulates the ATP phosphorylation of a chick intestinal brush-border membrane protein of molecular weight (MW) 84,000. The phosphate is attached to the protein through a serine or threonine residue. The reaction is stimulated by Ca^{2+} but does not require Mg^{2+}, and kinetic studies showed that 1,25-$(OH)_2D$ acts on this process by increasing the number of sites rather than the affinity of the substrate for the phosphate group. This phosphorylated protein has similar characteristics to those of the intestinal membrane protein whose synthesis is stimulated by 1,25-$(OH)_2D$.

The realization that more intestinal components than CaBP are involved in vitamin D-stimulated Ca absorption[4–6] gave fresh impetus to the search for their identification. 1,25-$(OH)_2D$ stimulates the synthesis of two brush-border proteins[7,8], in addition to the cytoplasmic CaBP[9] and a recently described mitochondrial protein[10]. One of these brush-border proteins is actin[11] and the other has a MW of 84,000. More evidence is required before the latter protein and the one undergoing ATP phosphorylation can be regarded as identical but it seems unlikely that there are two proteins of very similar molecular size in the intestinal brush border which are affected by vitamin D. We refer to the protein which undergoes phosphorylation as vitamin D-responsive protein (DRP). There have been preliminary reports of 1,25-$(OH)_2D$-dependent phosphorylation of intestinal brush-border membranes[12,13].

Following the incubation of chick intestinal brush-border membranes in a buffer containing [γ-^{32}P]ATP and Mg^{2+} for short periods of time, many of the protein components become phosphorylated (Fig. 1*a*) but in the absence of Mg^{2+} only one protein (MW 84,000) is phosphorylated (Fig. 1*b*). The phosphorylation reaction was present in intestinal brush borders or the membranes and core fractions derived from them. Treatment of the phosphorylated DRP with hydroxylamine did not release the phosphate from the protein (Fig. 1*c*) indicating that the product of this reaction is not an acyl phosphate of the type found in ATPases[14]. Furthermore the phosphorylated protein was stable to 5% trichloroacetic acid at 95 °C for 5 min but was hydrolysed by 1 M NaOH in the same conditions, which suggests that the phosphate acceptor in the protein is serine or threonine[15]. In incubations containing the brush-border fraction the rate of formation of phosphorylated DRP increased for up to 10 min and then remained substantially unchanged for a further 10 min (Fig. 2). However, in the case of the brush-border membrane, DRP phosphorylation was complete within 10 s, with significant dephosphorylation occurring over the next 10 min (Fig. 2). The effect of varying ATP levels on the initial phosphorylation rate of the brush border and its component

0028-0836/81/070600-03$01.00

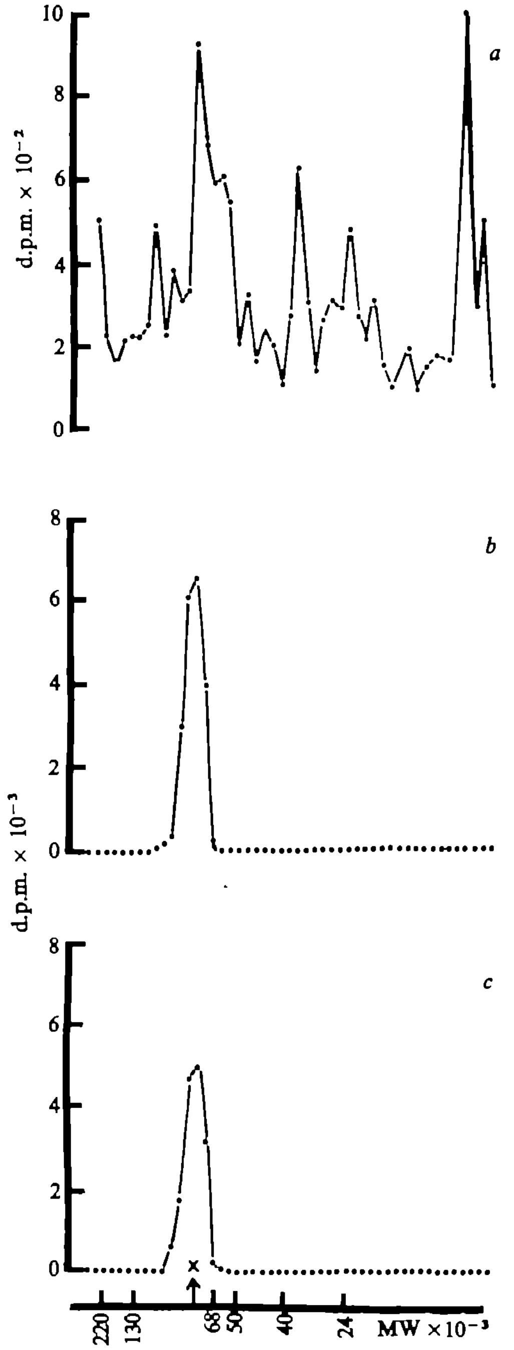

Fig. 1 Chick intestinal brush borders were prepared[8], washed twice in 40 mM Tris-HCl, *p*H 7.4, and resuspended in this buffer for storage in liquid N_2 before use. *a*, The brush borders (100 μg) were incubated at 0 °C in a medium (50 μl) of 40 mM Tris-HCl, *p*H 7.4, 2.5 mM Mg^{2+} and 2.5 μCi [γ-^{32}P]ATP for 30 s. The reaction was stopped with a dissociating solution (50 μl) to give a final concentration of 12 mg Tris, 15 mg dithiothreitol, 10 mg SDS and 100 μl glycerol ml^{-1} by heating at 70 °C for 30 min. *b*, The brush borders (100 μg) were incubated at 0 °C in a medium (100 μl) comprising: 5 mM theophylline, 10 mM NaF, 1 mM quercetin, 1 mM ouabain, 2.5 μCi[γ-^{32}P]ATP and 40 mM Tris-HCl, *p*H 7.4. The reaction was stopped with 1 ml 5% trichloroacetic acid (TCA), 2 mM H_3PO_4. The precipitate was dissolved in 100 μl of the dissociating solution to give the final concentrations as above. *c*, Brush borders incubated as in *b*, but the TCA precipitate was treated with 100 μl of 5 M hydroxylamine, *p*H 5.2, at 25 °C for 15 min before addition of 25 μl of dissociating solution (to give the appropriate concentration as above) and heating at 70 °C for 30 min. The proteins were fractionated by discontinuous gel electrophoresis[11]. The gels were sliced in 1-mm sections and ^{32}P measured in a liquid scintillation counter. ×, Position of 84,000-MW protein[7].

Table 1 Kinetic characteristics of the phosphorylation reaction undergone by intestinal brush border, and its membrane and core components

Treatment	Ca^{2+}	Brush border		Membrane		Core	
		V_{max}	K_m	V_{max}	K_m	V_{max}	K_m
−D	−	0.09	0.51	0.88	1.01	0.98	0.26
−D	+	0.21	1.23				
+D	−	0.60	0.47	3.49	0.78	2.04	0.27
+D	+	1.03	1.16	3.03	1.97	1.97	0.77
+1,25-$(OH)_2D_3$	−	0.25	0.49	1.76	1.09	1.11	0.27
+1,25-$(OH)_2D_3$	+	0.48	1.09				

Intestinal brush borders and their membrane and core components were prepared as described in the legends to Figs 1, 2. Incubations were carried out and stopped as described in Fig. 2 legend except that 0.25 mM Ca^{2+} was added to the incubation medium where indicated. The concentrations of ATP used were in the range 0.2–10 μM ATP. V_{max} (pmol per 10 μg per 15 s) and K_m (μM) values for the three fractions were obtained from a Lineweaver–Burke analysis of the initial velocities measured from 0–15 s. −D, vitamin D-deficient birds; +D, vitamin D-deficient birds treated with 12.5 μg of vitamin D_3 for 72 h before killing; +1,25-$(OH)_2D_3$, vitamin D-deficient birds treated with 125 ng of 1,25-$(OH)_2D_3$ for 4 h before killing.

parts is shown in Table 1. Greater phosphorylating activity was detected in the two components than in the whole brush border. The V_{max} of the reaction using the membrane and core fractions was almost sixfold and threefold, greater, respectively, than the V_{max} achieved by the brush borders.

A notable feature of this phosphorylation reaction is the lack of a requirement for Mg^{2+}. Brush borders from the intestine of vitamin D-replete chicks incubated in the usual medium continued to phosphorylate the DRP at an unchanged rate in the presence of EDTA or *trans*-1,2-diaminocyclohexanetetraacetic acid, a specific chelator of Mg^{2+}. However, the data in Table 1 show that Ca^{2+} stimulates the initial phosphorylation rate of the brush-border fraction but not of the derived membranes. The V_{max} of the reaction using the brush-border fraction was increased by about 70% and the K_m increased from 0.47 μM to 1.16 μM. In the case of the membrane fraction, the addition of Ca^{2+} had no effect on the V_{max} of the reaction but increased the K_m from 0.78 to 1.97 μM. Incubations carried out with brush borders, their membranes or their cores, from the intestine of vitamin D-deficient chicks showed that the initial DRP phosphorylation rate was significantly reduced compared with the activity shown by the same cell fraction from either vitamin D-replete birds or deficient chicks dosed with 1,25-$(OH)_2D_3$ (Table 1). This decrease in phosphorylation rate was reflected in a reduced V_{max} for the reaction, but the K_m for the reaction was virtually unchanged by the vitamin D status of the birds. An increase in the initial phosphorylation rate of DRP is observed within 4 h of a dose of 1,25-$(OH)_2D_3$ to rachitic chicks.

ATPases, components of ion pumps in membranes, are very rapidly phosphorylated with the formation of an acylphosphate intermediate[14]. Although the very rapid rate of phosphorylation occurring with the membrane fraction is typical of that found with ATPase enzymes, the evidence given above of the nature of the phosphate acceptors suggests a kinase type of phosphorylation reaction. If this is the case, the kinase is not of the class stimulated by cyclic nucleotides. The different rates of DRP phosphorylation using either brush borders or the membranes raises some intriguing questions concerning the control of the reaction and whether reaction rates are governed by the accessibility of the enzyme to the substrate. The greater level of activity shown by both the membranes and core fractions compared to the brush borders from which they were derived may indicate that the enzyme is on the inside of the brush-border membrane, or that there are factors[13] controlling the phosphorylation reaction which are released in formation of the membrane fraction so that the reaction proceeds very rapidly to

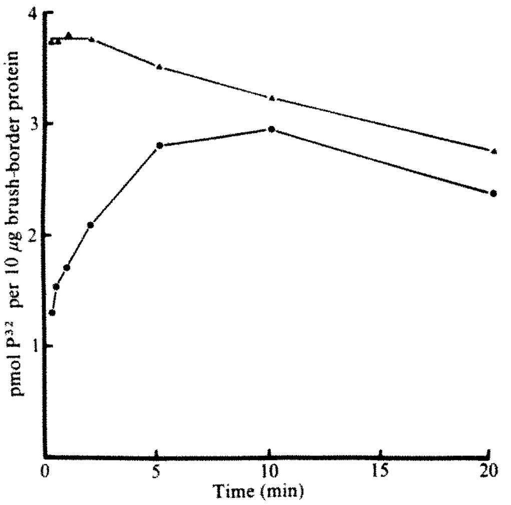

Fig. 2 Membranes of the chick intestinal brush borders were prepared by treating 2 mg of brush-border protein with 100 μl of 1% Triton X-100 in 40 mM Tris-HCl, *p*H 7.4, for 16 h at 4 °C. The solution was then centrifuged at 10,000*g* for 30 min—a pellet of the brush-border core material was produced, leaving the membranes suspended in the supernatant. The core material was resuspended in 100 μl of 1% Triton X-100 in 40 mM Tris-HCl, *p*H 7.4. The brush borders (5 μg of protein), or the membranes from 5 μg of brush-border protein, were incubated in the medium (50 μl) described in Fig. 1*b* legend plus 10 μM ATP, for the times indicated. the reactions were stopped with a solution (1.0 ml) of 5% TCA, 2 mM H_3PO_4 followed by addition of 500 μg of albumin as carrier. The precipitate was collected by centrifugation at 3,000 r.p.m. for 10 min, dissolved in 100 μl of 1 M NaOH at 0 °C and the protein re-precipitated with the above solution[16]. This precipitate was collected on Whatman glass fibre filters (GF/C), washed with 20 ml of ice-cold 10% TCA and the filters dried and ^{32}P measured with a scintillation counter. All assays were carried out in triplicate.

completion. Determination of the role of the DRP and its phosphorylation in vitamin D-stimulated calcium absorption must await further information but observations on the turnover of the phosphate group on phosphorylated DRP show that this is too slow for the phosphate to be involved in Ca absorption in a stoichiometric manner. If DRP is involved in Ca absorption, it is likely that the appropriate conformation requires the protein to be phosphorylated. These results indicate for the first time that ATP may be important in the response of the intestine to 1,25-$(OH)_2D$ but that the proportion of total cellular ATP involved is small.

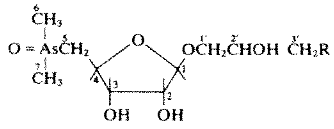
Arseno-sugars from brown kelp (*Ecklonia radiata*) as intermediates in cycling of arsenic in a marine ecosystem

J. S. Edmonds & K. A. Francesconi

Western Australian Marine Research Laboratories, PO Box 20,
North Beach, Western Australia 6020

The high concentration (relative to seawater) of arsenic in many marine animals eaten as human food has stimulated interest in the cycling of arsenic in the marine environment[1]. Although arsenic is present as arsenobetaine [$(CH_3)_3As^+CH_2COO^-$] in the western rock lobster[2] (*Panulirus cygnus*), the dusky shark[3] (*Carcharhinus obscurus*) and the school whiting[4] (*Sillago bassensis*) it is not clear what intermediate stages are involved in the biosynthesis of this compound from arsenate, the major form of arsenic in seawater[5]. We now report the isolation of the two main arsenical constituents of the brown kelp, *Ecklonia radiata*, and their identification as a 2-hydroxy-3-sulphopropyl-5-deoxy-5-(dimethylarsenoso)furanoside and a 2,3-dihydroxypropyl-5-deoxy-5-(dimethylarsenoso)furanoside. A *β*-ribo structure for the sugar system is strongly indicated in each case (*A* and *B* below).



A, R = $-SO_3H$
B, R = $-OH$

***Ecklonia* is the major organism that concentrates arsenic in the coastal ecosystem to which the western rock lobster and school whiting belong. It is clear that the compounds described here could readily be further metabolized to arsenobetaine and may well be the source of arsenobetaine in marine fauna associated with the region.**

Two water-soluble arsenic compounds (designated compounds *A* and *B*), which together accounted for 81% of the arsenic present in *Ecklonia*, were extracted from freshly collected alga (11 kg) with methanol. Compounds *A* and *B* were purified by chromatography on Sephadex LH-20 and ion-exchange Sephadex resins, and by HPLC and preparative layer chromatography. 30 mg of compound *A* and 5 mg of compound *B* were obtained as colourless syrups. Compound *A* was acidic and contained sulphur whereas compound *B* lacked sulphur and showed neither strongly acidic nor strongly basic character. Compound *A* contained: C, 26.9%, H, 5.3%; As, 17.5%; S, 7.5%. $C_{10}H_{21}O_9AsS$.$3H_2O$ requires: C, 26.9%; H, 6.0%; As, 16.8%; S, 7.2%. Compound *B* contained: As, 20.0%. $C_{10}H_{20}O_7As.3H_2O$ requires: As, 19.6%. The IR spectrum of compound *A* showed a strong absorbance at 845 cm^{-1} indicating the presence of an arsine oxide[6]. The IR spectra of *β*-ribose and 2,3-dihydroxy-1-propane sulphonic acid lacked absorbances in this region. The structures of compounds *A* and *B* were determined chiefly by NMR considerations.

The 270-MHz ^1H NMR spectra of compounds *A* and *B* (Table 1) differed substantially in only two respects. First, the eight-line (AB part of an ABX system) centred at δ 3.09 in the spectrum of compound *A* was replaced by a similar eight-line system centred at δ 3.63 in the spectrum of *B*; second, the three-proton multiplet at δ 4.25 in *A* became a two-proton multiplet (centred at δ 4.27) in *B*, with the appearance of a one-proton multiplet at δ 3.91. Irradiation at δ 4.27 (compound *A*) resulted in the collapse to AB quartets of all three eight-line (AB parts of ABX systems) systems (δ 2.59, 3.09, 3.71). Thus, because of the coincidence of methine signals at δ 4.27, limited structural information was obtained. However, irradiation at δ

Compound *B*: CH_2OH CHOH $\mathit{CH_2}$ OH	3.57	¶

3.91 (compound *B*) resulted in the collapse to AB quartets of the two eight-line systems centred at δ 3.63 and δ 3.70. Irradiation at δ 3.63 or δ 3.70 caused simplification of the signal at δ 3.91. The remainder of the spectrum of compound *B*, which was almost identical to that of compound *A*, remained unaltered by these spin-decoupling experiments.

It followed that each compound could be regarded in two parts—a three-carbon moiety in which the differences between compounds *A* and *B* lay, and the remainder of the molecule (shown by ^{13}C NMR, see below, to contain seven carbon atoms). Both ^1H NMR and ^{13}C NMR (Table 2, compound *A* only) demonstrated the identity of the three-carbon moiety as 2,3-dihydroxypropane sulphonic acid in compound *A* and 1,2,3-trihydroxypropane in compound *B*. These identifications were confirmed by TLC (compound *A*) and HPLC (compound *B*) examination of the acid hydrolysates. The part of the 270-MHz ^1H NMR spectra which was identical for compounds *A* and *B* and assigned to the seven-carbon moiety contained signals attributable to two methyl groups and one methylene attached to arsenic. The rest of the spectrum (due to CH signals) was consistent with the presence of a sugar system. The 20.1-MHz ^{13}C NMR data for compound *A* confirmed the presence of a $C_{10}H_{17}$ skeleton (two CH_3 groups, three CH_2, five CH). Shieldings of the two methyl groups and the one methylene indicated that they were bound to arsenic. Shieldings of two methylenes and one methine were consistent with the presence of the sulphopropanediol residue as discussed above. The remainder of the methine shieldings demonstrated the presence of a furanoside with a transoid substitution arrangement at C-1 and C-2 (ref. 7). Of the possible candidates (β-xylo-, α-arabino-, β-ribo- and α-lyxo-), the closest match to the observed shieldings was obtained for a β-ribo- system when the effects on C-4 and C-3 of the postulated 5-deoxyfuranoside structure had been taken into account. However, the shieldings of an α-lyxoside were not sufficiently different from the observed values to eliminate completely an α-lyxo- in favour of a β-riboside system. Hydrolysis with aqueous sodium hydoxide resulted in the release of dimethylarsinic acid from both compounds *A* and *B*. Heating compound *A* with concentrated hydrochloric acid also resulted in the production of dimethylarsinic acid. In both experiments the remainder of the molecule was too far degraded for chemical identification of the sugar.

---

* The integrations of the signals were in accordance with their assignments.

† Only results of the most informative decoupling experiments are shown. In each of these no other part of the spectrum was altered. Irradiation, subsequently, at the chemical shifts of the simplified signals in these experiments resulted in the expected alterations to the spectrum at δ 4.25 (compound *A*) and δ 4.27 and δ 3.9 (compound *B*), but such changes were not amenable to simple analysis. Irradiation at the chemical shifts of other signals either had no effect or the altered signals were too close to the position of irradiation for reliable interpretaion.

‡ The assignments of CH2 and CH3 are uncertain and may be reversed.

§ Not amenable to first order analysis.

‖ In furanoid systems where H-1 and H-2 are transoid the observed coupling constant approaches zero (ref. 15).

¶ Recorded at 60 MHz and not amenable to first order analysis.

Table 2 20.1 MHz ^{13}C NMR data for compound *A* and model compounds

Compound *A*			Model compounds

CH	2′	66.9‡	HO CH_2 *C*HOH CH_2SO_3H		68.4
CH_2	3′	54.3	HO CH_2 CHOH $\mathit{C}H_2SO_3H$		54.0

* CH_3, CH_2 and CH groups were identified by off resonance decoupling.

† The differences in shieldings for C-3 and C-4 of compound *A* and the C-3 and C-4 of methyl β-ribofuranoside are accommodated by the 5-deoxy structure postulated for the former. It is assumed that the less electronegative substituent ($-CH_2As$) at the 5 position will produce effects on the shieldings of C-3 and C-4 analogous to (for example) the differences between the shieldings of C-4 and C-5 in glucose and 6-deoxyglucose[16]. Thus, differences in shielding of about 5 p.p.m. for C-3 and C-4 (in opposite directions) when compared with methyl β-ribofuranoside are accommodated.

‡ The differences in shieldings for C-1′ and C-2′ and the relevant carbons in the model compound are accounted for by the formation of the glycosidic linkage through $-C1'H_2O-$.

§ Ref. 7.

Compounds *A* and *B* are quite similar to isofloridoside (2,3-dihydroxypropyl α-D-galactopyranoside), a constituent of some red algae[8]. Free 2,3-dihydroxy-1-propane sulphonic acid has been reported as a component of algae[9]. However, compounds *A* and *B* are apparently unrelated to the arsenophospholipids and related de-acylated compounds containing a trimethylarsonium lactate residue demonstrated by Cooney *et al.*[10] to be present in unicellular marine algae exposed to radiolabelled arsenate. Such compounds were not detected in *Ecklonia.*

Evidently, *Ecklonia* is processing its arsenate uptake by conversion to the sugar derivatives described here. Benson has speculated[11] that algae have evolved the capacity to detoxify arsenate in marine waters low in phosphate. Western Australian coastal waters are notably deficient in phosphate[12]. The two compounds reported here can readily be envisaged as being intermediates in the production of dimethylarsinic acid (shown by Andreae[5] to be present in marine waters of the photic zone) and arsenobetaine. The latter would require further reduction and methylation of the arsenic atom and oxidation at the C-4 of the sugar residue. Such conversions might well be mediated by the microflora of the sediments contributed to by decaying *Ecklonia,* and arsenobetaine may enter the food chains, eventually reaching rock lobsters and whiting via detritovores. We are now studying these processes.

We thank Dr L. T. Byrne for ^{13}C NMR spectra, Dr A. J. Jones for 270-MHz ^{1}H NMR spectra and discussions, Drs D. A. Hancock and H. E. Jones for their interest, and Professor D. W. Cameron for much helpful discussion and encouragement. C, H microanalyses were performed by the Australian Microanalytical service.

Active site and catalytic mechanism of phospholipase A_2

Bauke W. Dijkstra, Jan Drenth & Kor H. Kalk

Laboratory of Chemical Physics, University of Groningen,
Nijenborgh 16, 9747 AG Groningen, The Netherlands

The esterolytic enzyme phospholipase A_2 specifically splits the 2-acyl linkage of phosphoglycerides[1] in a calcium-dependent reaction. In the pancreas the enzyme occurs as a zymogen which is activated on secretion into the duodenal tract by the removal of seven amino acid residues from the N terminus by trypsin[2,3]. Having refined our X-ray analysis of the crystal structure of bovine pancreatic phospholipase A_2 from 2.4 Å (ref. 4) to 1.7 Å resolution[5], we now describe how the structure of the molecule may account for the specificity of the enzyme and for the sudden and dramatic change in activity when the substrate concentration passes the critical micelle concentration[6].

Analysis of the structure at 2.4 Å resolution[4] showed that the active site is in a depression at the molecular surface. The essential residue, His 48, which is directly involved in catalysis[7], is located in this region (Fig. 1). The ε-N atom of His 48 is in close contact with one of the carboxylate oxygens of Asp 99 (for residue numbering see ref. 8). The wall of the active site is covered with hydrophobic residues: Phe 5, Ile 9, Phe 22, Ala 102 and 103, Phe 106 and the disulphide bridge between Cys 29 and Cys 45. All these residues are invariant in the phospholipase A_2 sequences known so far, except for an occasional replacement of Ala 103 by a Val (ref. 9) and Phe 22 by a Tyr (refs 9–13). The essential calcium ion is also in this region, but near Asp 49, not Asp 99 as previously suggested[4].

The interior of the active site mainly consists of invariant hydrophobic residues, whereas the entrance is composed of variable residues, hydrophobic and polar (Fig. 2).

Although Asp–His couples occur frequently in protein molecules, the presence of this couple in the active site of phospholipase A_2 suggests a similarity to the proton relay system in the proteolytic serine enzymes. In these proteases—as in all proteolytic enzymes[14,15]—there are three main stages in the splitting of the peptide bond: (1) nucleophilic attack by the serine OH; (2) proton transfer by the histidine's imidazole ring; and (3) fixation and stabilization of the substrate's carbonyl oxygen by slightly positively charged NH groups. In deacylation a water molecule replaces the serine OH group as the nucleophile. Phospholipase A_2 has exactly the same configuration in its

0028-0836/81/070604-03$01.00

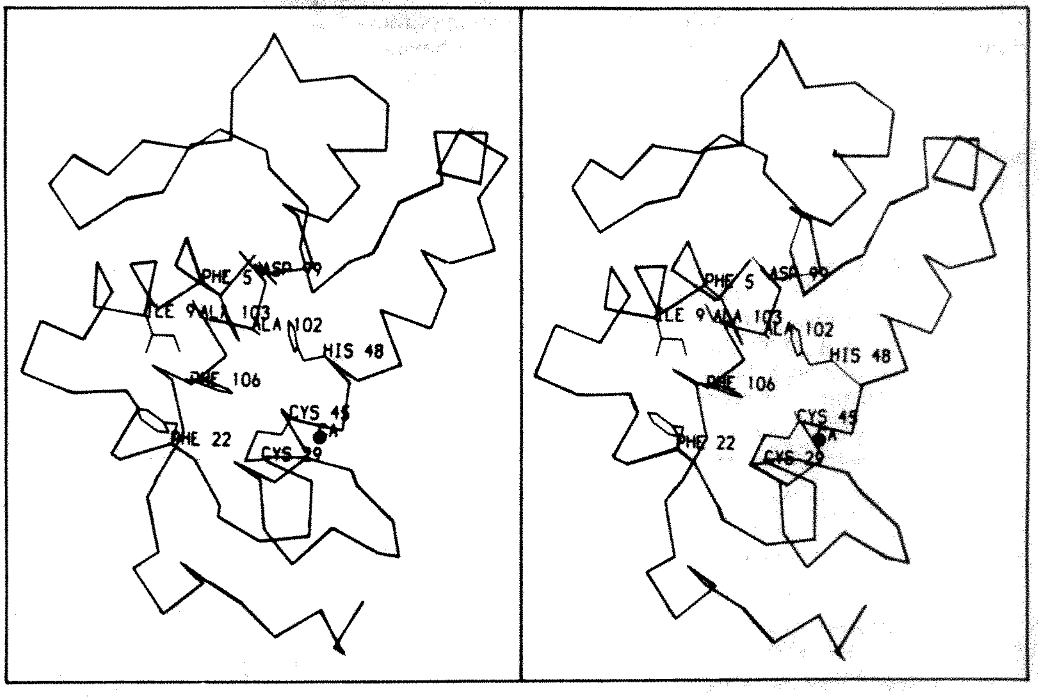

Fig. 1 A stereo pair showing the essential active site residues. The black dot is the calcium ion.

active site but has a water molecule instead of a serine OH. This water molecule is in the plane of the imidazole ring 3.1 Å from His 48δ-N1. Thus, the ester hydrolysis by phospholipase A_2 seems to be identical to the deacylation step—which is also ester hydrolysis—in the serine proteases, the only difference being that in the latter the substrate is covalently bound to the enzyme. Fixation and stabilization of the carbonyl oxygen atom of the ester bond might occur in phospholipase by means of the NH of Gly 30 and possibly by the calcium ion. This ion is also available for binding the substrate's phosphate group, especially because it has only one carboxyl group (Asp 49) in its coordination sphere. Substrate binding studies are required to test this hypothesis experimentally.

Phospholipase A_2 has a much higher activity towards aggregated than single phospholipid molecules (up to 1,000, ref. 16). Some workers attribute this effect to an entropic factor—a preferred orientation of the enzyme with its active site directed to the substrate layer[17], or a preferred substrate conformation[16]. Others explain the effect by a change in enzyme conformation at the active site as a result of the binding to the substrate layer[6,18]. With only the enzyme's native structure available the conformational change cannot be verified. However, we do know the part of the enzyme's molecular surface which interacts with the micelle and also that a complementarity exists between the active site and the conformation of the substrate molecules in the aggregated state.

If the enzyme has its active site directed towards the micellar surface three distinct regions for interaction with the micelle can be discerned (Fig. 2). One region comprises residues in a ring surrounding the entrance to the active site, the other two regions are at the extremes of the molecule. Several residues in these regions—those at positions 3, 6, 19, 31 and 69 (ref. 19)—have been implicated in the interaction with micellar substrates. Although none of these regions shows residues conserved at homologous positions, the hydrophobic or polar character of these residues is maintained. A special feature is the excess of at least two basic over acid residues, suggesting salt bridge formation with the phosphate groups in the micelle which would thus orient the enzyme with respect to the micelle surface. This is in agreement with a proposal by Brockerhoff and Jensen[17].

Crystal structure and NMR studies have shown that phospholipid molecules in micelles or pseudo-micelles have a unique conformation[20]. Their main features are parallel and extended fatty acid chains, with a kink in the second chain at the α-C atom. The shape of the phospholipase A_2 active site is such that a substrate molecule in this conformation can easily enter the active site and approach His 48 with its scissile bond. A conformational change in the substrate molecule is not required, and model building studies indicate that the kink is an absolute requirement for fitting. The calcium ion in that case is available for binding the phosphate group, and the active site holds between four and six CH_2 groups of each fatty acid chain. This shows—as previously suggested[16]—that besides the orientation of the enzyme molecule a second entropic advantage is the presence of the right substrate conformation in aggregates like micelles.

Our crystallographic studies have also analysed the structure of bovine pancreatic prophospholipase A_2. This precursor does not show the rate increase towards aggregated substrate. Although the structure of porcine pancreatic prophospholipase A_2 at 3 Å resolution has been reported[15], it was later

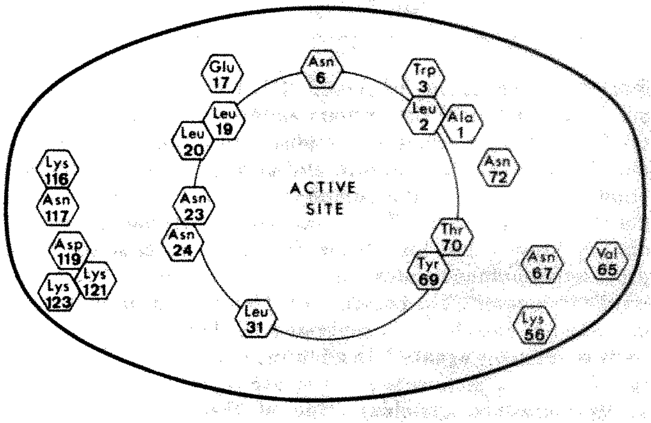

Fig. 2 Schematic representation of the face of the molecule which is directed towards the phospholipid layer. The residues in boxes, in the bovine enzyme, have their side chain pointing to the substrate layer. Residue 1 is incorporated because of its free NH_2 which is essential for binding. One set of residues is in a ring surrounding the entrance to the active site. Two other sets are on the left and on the right.

found to have been based on an incorrect interpretation of the electron density map. Recently, high-quality crystals of bovine prophospholipase A_2 have become available, and preliminary crystallographic results indicate differences with the enzyme itself at the N terminus due to an increased mobility in this region. This agrees with studies by Slotboom *et al.*[21] showing that a precise architecture of this region is required for micelle binding.

We thank Professor G. H. de Haas and his coworkers for their cooperation, Dr W. G. J. Hol for stimulating discussions and Mrs C. A. Torfs-van Cotthem for her contributions. Assignment of the disulphide bonds of leukocyte interferon

Ronald Wetzel

Genentech Inc., 460 Point San Bruno Boulevard,
South San Francisco, California 49080

Nucleotide sequencing of cloned cDNA can lead to rapid and precise prediction of the primary amino acid sequence of gene products, but it cannot establish such post-translational modifications as the existence and arrangement of disulphide bonds. For example, the complete sequences of at least one fibroblast[1] and seven[2–4,12] leukocyte interferon genes are already known, but knowledge derived from analysis of the proteins is confined to information on the N-termini[5–8] and some tryptic fragments[9]. The presence of at least one disulphide bond in leukocyte interferon is suggested by that molecule's sensitivity to reducing agents[10]. In addition, comparison of all leukocyte interferon gene sequences so far reported indicates four highly conserved cysteines. One of these genes has been engineered for efficient direct expression in *Escherichia coli*[4] and we have purified the gene product, leukocyte interferon A (IFN-αA, Fig. 1) from bacterial extracts to a single species of molecular weight (MW) 19,400[13]. I report here the determination of the disulphide bonds of the purified protein by analysis of tryptic fragments. The results indicate that Cys 1 is bonded to Cys 98, and Cys 29 is bonded to Cys 138.

Fig. 1 The amino acid sequence of IFN-αA predicted from the nucleotide sequence of the gene in the plasmid directing its expression in *E. coli*[4]. The cysteine residues are underlined.

Digestion of native IFN-αA with trypsin produces a mixture of fragments which can be partially resolved by HPLC as shown in Fig. 2*a*. Treatment of part of the tryptic digest before HPLC analysis with dithiothreitol (DTT) yields the profile shown in Fig. 2*b*. At least five significant peaks are lost on DTT reduction, indicating the presence of a disulphide bond in each. Further experiments showed that peak 1 is associated with one of the disulphide bonds and peaks 2–5 are associated with the other.

At increasing trypsin/interferon ratios, peaks 2 and 3 increase in size relative to peaks 4 and 5 indicating that they are related by the presence of a resistant trypsin cleavage site. At a trypsin/interferon ratio of 1:10, peaks 4 and 5 almost disappear. The fact that the 2, 3 doublet and the 4, 5 doublet wax or wane in unison suggests that 2 is related to 3 and 4 is related to 5.

Samples of peaks 1, 4 and 5 (3–12 μg) were subjected to amino acid analysis. The results were compared with calculated values for all possible disulphide-containing peptides predicted from the nucleotide sequence of the gene (Table 1). Also

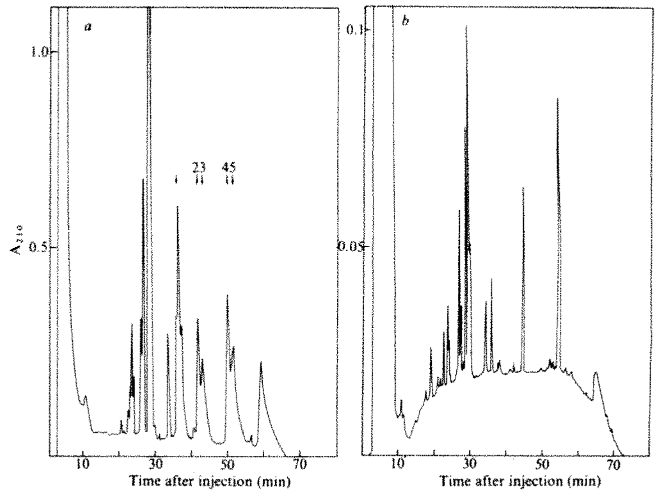

Fig. 2 HPLC of a trypsin digest of IFN-αA. A solution of 500 μg of native IFN-αA in 400 μl of 50 mM sodium phosphate, *p*H 7.8 was incubated with 8 μg of TPCK-trypsin (Worthington) for 24 h at room temperature. Analysis was on an Altex ODS-Ultrasphere column with a linear gradient of acetonitrile in 0.1% aqueous trifluoroacetic acid[11]. *a*, One half of the digest was injected and individual peaks collected. *b*, 20 μl of the digest were added to 20 μl of 7 M urea, 50 mM DTT and incubated for 2 h at room temperature before injection on the same HPLC system.

Cystine peptides are named according to the cysteine residues they contain, with 98^+ denoting the Cys 98 peptide obtained when the Lys–Phe bond after Lys 83 is not cleaved. Analyses were obtained from AAA Labs, Mercer Island, Washington.

* Values for these amino acids were not used in calculating compositions because cysteine and tryptophan were not determined in the amino acid analysis.

included as possible structures were the peptides which would be generated from the lack of a trypsin cut at the Lys–Phe bond after Lys 83. Analysis of the results indicates that peak 1 corresponds to a peptide with a disulphide bond between Cys 29 and Cys 138, and peaks 4 and 5 correspond to a peptide with a disulphide bond between Cys 1 and Cys 98 which was not cleaved by trypsin after Lys 83. Comparison of the analysis of peak 5 with that of peak 4 shows several minor differences, which may be attributed to experimental error due to small sample size. Peaks 4 and 5 could differ in the extent to which they have undergone deamidation of amide side chains. Such heterogeneity would not be unexpected, and would not show up in the analysis of an acid hydrolysate.

The presence of the two disulphide bonds, one of them involving Cys 1, suggests that an early cysteine should be present in the mature sequences of other leukocyte interferons, a postulate contradicted by some published N-terminal protein sequence data[5,8] but consistent with all reported DNA sequences. Since two of the three cysteines of fibroblast interferon[1] are conserved in the sequence of leukocyte interferon, and since these two conserved cysteines form one of the disulphides in leukocyte interferon, it seems likely that a disulphide bond exists between Cys 31 and Cys 141 of the fibroblast molecule. Regardless of the presence and arrangement of a disulphide bond in fibroblast interferon, there can be no more than one, and this work thus demonstrates a structural difference between the two kinds of acid-stable interferons.

Unique transforming gene in carcinogen-transformed mouse cells

Ben-Zion Shilo & Robert A. Weinberg

Center for Cancer Research and Department of Biology,
Massachusetts Institute of Technology, Cambridge,
Massachusetts 02139

Observations from various biological systems suggest that chemical carcinogens transform cells by causing somatic mutations through interacting with DNA[1–5]. These observations raise several fundamental questions regarding the nature of the transforming genes that are the target of the carcinogens. For example, are there unique target gene(s) for chemical carcinogens, or are there multiple potential targets, any of which, when altered, can induce the transformed phenotype? This problem has been approached previously by comparing the rate of transformation by chemical carcinogens with the rate of appearance of dominant mutations in unique cellular genes encoding selectable markers. The results suggested a limited number of targets for transformation, since transformation occurred at a rate that was only 10–100 times greater than the appearance of ouabain-resistant mutants[6–8]. These results, however, are only rough estimates, because the optimal conditions for induction of transformation and the induction of mutations are known to differ[6]. In addition, lesions other than point mutations caused by carcinogens, such as frameshifts, may induce transformation efficiency but not ouabain resistance. We now present an alternative experimental approach to estimating the number of targets for chemical carcinogens, based on the fact that DNAs of certain chemically transformed cell lines can induce the appearance of foci when transferred on to NIH3T3 cells[9]. These DNAs were treated with a variety of restriction endonucleases before testing their transforming activities by DNA transfer. We have found the same pattern of sensitivity and resistance to inactivation by different endonucleases in all DNAs studied, suggesting that the same transforming gene is being transferred in all cases.

0028–0836/81/070607–03$01.00

Table 1 The effect of restriction enzyme cleavages on the transfections of DNAs of 3-MC-transformed cells

DNA source	Origin of donor line	No enzyme	Foci				
			*Bam*HI	*Eco*RI	*Hin*dIII	*Xho*I	*Sal*I
MCA16-5	A focus derived from transfection of DNA from the 3-MC-transformed C3H10T1/2 line MCA16 (ref. 17)	73, 58	14, 25	0	0	33	50
MCA5	3-MC-transformed C3H10T1/2 cells[18]	5, 6, 8	7	0	0	4	8
MB66MCAad36	3-MC-transformed C3H10T1/2 cells	15	14, 9, 9	0	0	34	6
MC5-5-6	A focus derived from transfection of chromosomes from the 3-MC-transformed BALB3T3 line MC5-5 (ref. 19)	60	17	0	0	6	5
NFS-1	A focus from transfection of NFS mouse liver DNA	17, 26	0	0	ND	ND	ND
NIH3T3	NIH3T3 cells	0	0	ND	ND	0	ND

In each transfection 75 μg of DNA were applied to 1.5×10^6 NIH3T3 cells, and the appearance of foci was scored 14 d later. The transfection efficiency of the DNA following digest with enzymes that are non-cutters is occasionally reduced by a factor of two to three. We do not understand the basis for this reduction. ND, not determined.

DNA-mediated gene transfer has recently been applied to the study of chemical carcinogenesis[9]. DNAs from a variety of chemically transformed mouse lines were applied to NIH3T3 cells, and their ability to induce foci of transformed cells was scored. DNAs extracted from five lines that were independently transformed *in vitro* by 3-methylcholanthrene (3-MC) were shown to induce the appearance of foci[9], thus demonstrating directly that the DNA of these chemically transformed cells was altered relative to the DNAs of untransformed mouse cells. These alterations were probably of central importance in carcinogenesis, as they resulted in the generation of potent transforming genes not detectable in normal cellular DNA.

The naked DNA being introduced into NIH3T3 cells in these transfection assays can be biochemically modified before its transfer by treatment with site-specific endonucleases. An enzyme that cuts within a functionally essential region of the transforming gene would be expected to abolish the transforming ability of the DNA. Conversely, enzymes cleaving only outside the functionally important regions of a gene should leave the biological activity of the DNA unaffected. It is also essential for the initiation of molecular cloning of the gene[10] to obtain information about enzymes that are 'cutters' or 'non-cutters' of the transforming activity.

Because of the random occurrence of cleavage sites for restriction enzymes, one cannot predict the presence of such sites within a given gene. This randomness confers on each gene a specific pattern of sensitivity or resistance to inactivation by a series of restriction enzymes applied to the DNA encoding the gene. It is highly unlikely that two genes of unrelated sequence will have an identical spectrum of sensitivities and resistances to many restriction enzymes. Such enzyme cleavage before transfection, therefore, provides a useful method for comparing the structures of transforming genes being transferred from the different chemically transformed donor cell lines. We have used this procedure to analyse transforming genes of four of the 3-MC-transformed mouse cell lines, either by cleavage of the DNAs of the transformed donor cells or by cleavage of the DNAs of foci derived from transfection of the donor cell DNAs. This latter step was made possible by our earlier demonstration that the transforming genes can be serially passaged from donors to recipients through several cycles of transfection[9].

Before transfection, each of the four DNAs was cleaved with one of a series of five restriction enzymes. Each of these enzymes recognizes a different hexanucleotide sequence at its site of cleavage. In every case the completeness of cleavage by an enzyme was determined by taking an aliquot of the reaction mixture, adding a small amount of a DNA of defined sequence and monitoring the digestion products of that sequence by gel electrophoresis. An example of this assay is shown in Fig. 1. In every transfection, a positive control of uncleaved DNA was included in parallel. We demanded significant numbers of foci from cultures transfected with the positive control DNA before regarding the results of a transfection as interpretable.

The results of these experiments are summarized in Table 1. The data indicate an identical pattern of sensitivity and resistance to the five restriction enzymes among the DNAs of the four lines tested. We conclude that the transforming genes of the four mouse lines have a high probability of being associated with an identical set of nucleotide sequences. The interpretation of these results is even more compelling if the average cleavage frequencies in mammalian DNA of the different enzymes used are taken into account. *Bam*HI, *Eco*RI and *Hin*dIII cleave mammalian DNA into fragments which average 4 kilobase pairs in mass. Among the enzymes of a similar cutting frequency tested (including *Bgl*II and *Xba*I for MCA16-5 DNA; data not shown), only *Bam*HI did not inactivate the transforming activity of the DNA. It was thus striking that the same frequently cutting enzyme was not a cutter for any of the four DNAs.

The following statistical considerations support the conclusion that the same transforming gene is being transferred in the four cases. The probability that a gene in the 10-kilobase pair size range would be inactivated by cleavage with an enzyme that cuts on average every 4 kilobase pairs is about 0.8. Conversely, the probability of that gene being inactivated by an enzyme that cuts every 30 kilobase pairs (such as *Xho*I or *Sal*I) is only 0.3. Thus, the probability of two lines displaying the same pattern we observed for the five enzymes would be $0.2(0.8)^2(0.7)^2 = 0.06$. The probability of four lines displaying the same pattern would be $(0.06)^3 = 2 \times 10^{-4}$. Therefore, the chances of the results we observed occurring coincidentally are as low as 2×10^{-4}.

The results derived from the non-cutting enzymes such as *Bam*HI might be interpreted differently—that these non-cutting enzymes did destroy the activity of the gene observed on transfection of an uncleaved DNA, while at the same time creating a novel, equally potent transforming gene as a direct consequence of cleavage of normal cellular sequences at a critical target site. This possibility becomes more likely in the light of recent work suggesting that random breakage of normal cellular DNA induced by sonication was able to create at a low frequency novel, transfectable transforming genes[11]. We therefore examined the effects of cleavage of normal mouse DNA (extracted from NIH3T3 cells) by *Bam*HI or *Xho*I. Because no foci were observed following transfection (Table 1), we concluded that cleavage by these enzymes does not activate latent transforming genes which may exist in normal cellular DNA.

Additional data support the conclusion that the spectrum of resistance and sensitivity to specific endonucleases is unique to the 3-MC-transformed lines. A transformed NIH3T3 cell line, which was derived after exposure to normal mouse liver DNA, possesses a transforming gene which is inactivated by *Bam*HI (Table 1), in contrast to the 3-MC-transformed lines. A rat neuroblastoma gene exhibits a totally different pattern of resistance and sensitivity to the enzymes tested here[12]. Finally, in a series of murine retrovirus genomes whose transforming genes have been characterized by transfection into NIH3T3 cells, each exhibits a unique pattern of inactivation by the different site-specific endonucleases[13–16]. The characteristic pattern of the 3-MC-transformed lines observed here is thus a reflection of the physical structure of the gene being transferred and is not due to an effect of these enzymes on the general process of transfection.

The present conclusions on the identity of the transforming genes in the four 3-MC-transformed lines will be strengthened when the respective transforming alleles are isolated as molecular clones. However, neither the present results nor the anticipated molecular cloning allow us to conclude that the transforming alleles observed in these cell lines were created as a direct result of exposure to 3-MC, the original carcinogen used. Rather, it is possible that in cells mutagenized by carcinogen, a second, independently occurring mutational event may occur on subsequent cell passage, which in turn results in the generation of the transforming genes described here.

Our conclusions regarding the multiplicity of potential transforming genes which can be activated by exposure to chemical carcinogens are limited to the spectrum of transformed lines that has been tested. They apply only to transformed mouse cells which are derived from exposure of monolayer fibroblast cultures to 3-MC *in vitro*. Because several 3-MC-transformed mouse fibroblast lines failed to yield biologically active DNA in transfections[9], the present results may be relevant only to a subset of 3-MC-transformed mouse fibroblasts. Nevertheless, the data suggest that the number of transforming genes induced by chemical carcinogens may be small, and that the molecular mechanisms of chemical transformation depend on activation of limited and unique pathways for transformation.

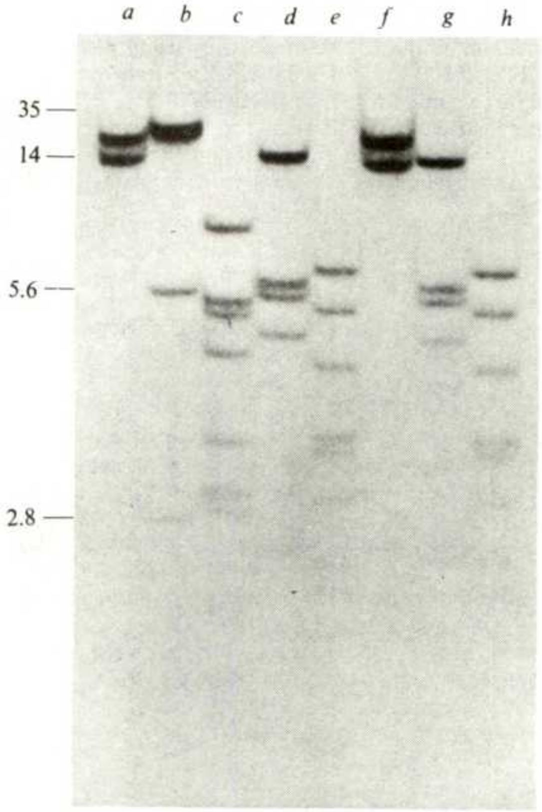

Fig. 1 Analysis of completeness of digestion of cellular DNAs by restriction endonucleases. Cellular DNA was incubated in restriction endonuclease buffer at a concentration of 20–50 μg ml^{-1}. After addition of the enzyme, a 50-μl aliquot was incubated with 50 pg of *in vivo* ^{32}P-labelled adenovirus 5 DNA (35 kilobase pairs). The reaction was incubated at 37 °C for 5 h and the aliquots run on a 1% agarose gel. The gel was fixed for 1 h in methanol, dried and exposed to X-ray film. The cleaved cellular DNA was treated with phenol and chloroform and ethanol precipitated before transjection. *a–e*, MB66MCA ad36 DNA digested with *Bam*HI, *Eco*RI, *Hin*dIII, *Xho*I and *Sma*I, respectively. *f–h*, MCA16-5 DNA digested with *Bam*HI, *Xho*I and *Sma*I, respectively. The molecular weights are given in kilobase pairs. The results of the transfection of the DNAs whose digests were monitored on this gel are given in Table 1.

We thank Chiaho Shih for his help in the transfections and for characterizing the rat neuroblastoma gene. This work was supported by the Rita Allen Foundation of which R.A.W. was a fellow and by NIH core grant CA14051 to S. Luria. B.S. is a Chaim Weizmann postdoctoral fellow.

Distribution of the insertion sequence IS1 in Gram-negative bacteria

Kate Nyman, Kenzo Nakamura*, Hisako Ohtsubo & Eiichi Ohtsubo

Department of Microbiology and *Biochemistry, Basic Health Sciences Center, School of Medicine, State University of New York at Stony Brook, Stony Brook, New York 11794

Translocation of DNA segments is a recombinational event seen in both eukaryotic and prokaryotic chromosomes, and it is thought to be involved in controlling gene expression and in the evolution of chromosomes[1,2]. In bacteria, insertion (IS) and transposable (Tn) elements[3] not only translocate their own DNA, but also promote the rearrangement of both bacterial chromosomes and the plasmic genomes carrying them. The insertion element IS1 is one such element which is 768 base pairs long[4–7]. IS1 is involved in the generation of deletion mutations and in the fusion of two different plasmid genomes[8–12]. It can also promote the translocation of DNA segments flanked by two copies of IS1 to give rise to transposable elements responsible for antibiotic resistance and enterotoxin production[13–16]. We report here the distribution of the IS1 sequence in various bacterial DNAs, particularly in the family Enterobacteriaceae. Comparison of the results with the phylogenetic relationship of these bacteria suggests that IS1 was transferred from one bacterium to another after their divergence and in some bacteria the copy number of IS1 increased by translocation. The increase in the number of copies of IS1 in bacteria may increase the probability of the genetic rearrangement responsible for the generation of resistance and enterotoxin plasmids, the existence of which is a serious problem in medical microbiology.

0028-0836/81/070609-04$01.00

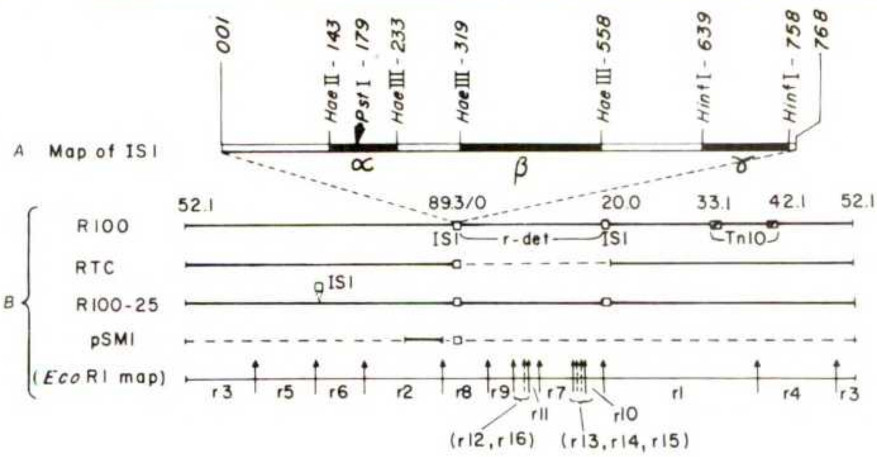

Fig. 1 *A*, Map of IS1, showing the locations of fragments used as hybridization probes. Italicized numbers indicate the coordinates of restriction endonuclease cutting sites, in nucleotides, from an end of IS1 (see ref. 6). The restriction endonuclease *Pst*I cuts IS1 at one site as indicated. *B*, Physical structures of the resistance plasmid R100 and its derivatives determined by the electron microscope heteroduplex methods[5,12,20]. All the molecules are actually circular duplexes, but the structures are displayed in a linear representation by cutting the circle at a point that lacks interesting features. All the numbers are distances in kilobases from a selected origin. Note that R100 carries two copies of IS1 (shown by open boxes) which flank the r-determinant region (r-det) containing genes responsible for resistance to chloramphenicol, sulphanilamide and streptomycin. R100 produces 16 fragments (named r with numbers) by *Eco*RI digestion, the locations of which have been determined as indicated at the bottom of the figure. The fragments, r1 and r8, contain IS1 sequences (see the gel pattern of some of the fragments shown in Fig. 2*A*). Plasmid RTC deletes the r-determinant region of R100 by recombination between the two IS1 sequences and therefore carries a single copy of IS1. This IS1 is carried by an *Eco*RI fragment of RTC, called r1′, which is a new fragment almost identical to r1. R100-25 has an additional insertion of IS1 which appears in the *Eco*RI fragment, r6, or R100 to give a new larger fragment, r6′ (see also Fig. 2*A*). pSM1 is a plasmid which deletes most of R100 but carries a copy of IS1. This plasmid was used for the isolation of the restriction fragments which are derived from inside IS1 and are used for the hybridization study.

From the nucleotide sequence of IS1 (ref. 6) the locations within the sequence of cleavage sites for restriction endonucleases such as *Hae*II, *Hae*III, *Pst*I and *Hin*fI were localized as shown in Fig. 1*A*. The DNA fragments, named α, β and γ, obtained by cleavage with any one or two of these enzymes, can be isolated from a small plasmid called pSM1, which contains one copy of IS1 (refs 6, 9), as shown in Fig. 1*A*. The 5′ end of both strands of these fragments was labelled using [γ-^{32}P]ATP and polynucleotide kinase, and the two single strands of the DNA fragment were separated as described by Maxam and Gilbert[17]. We examined whether the ^{32}P-end-labelled strands could hybridize specifically with restriction fragments containing IS1 sequences, by using plasmid DNAs such as RTC, R100 and R100-25, which are known to carry one, two and three copies of IS1, respectively. Figure 1*B* represents the physical structures of these plasmids, showing the locations of IS1 and the *Eco*RI restriction endonuclease cleavage sites. Figure 2*A* (*a–c*) shows an ethidium bromide-stained agarose gel

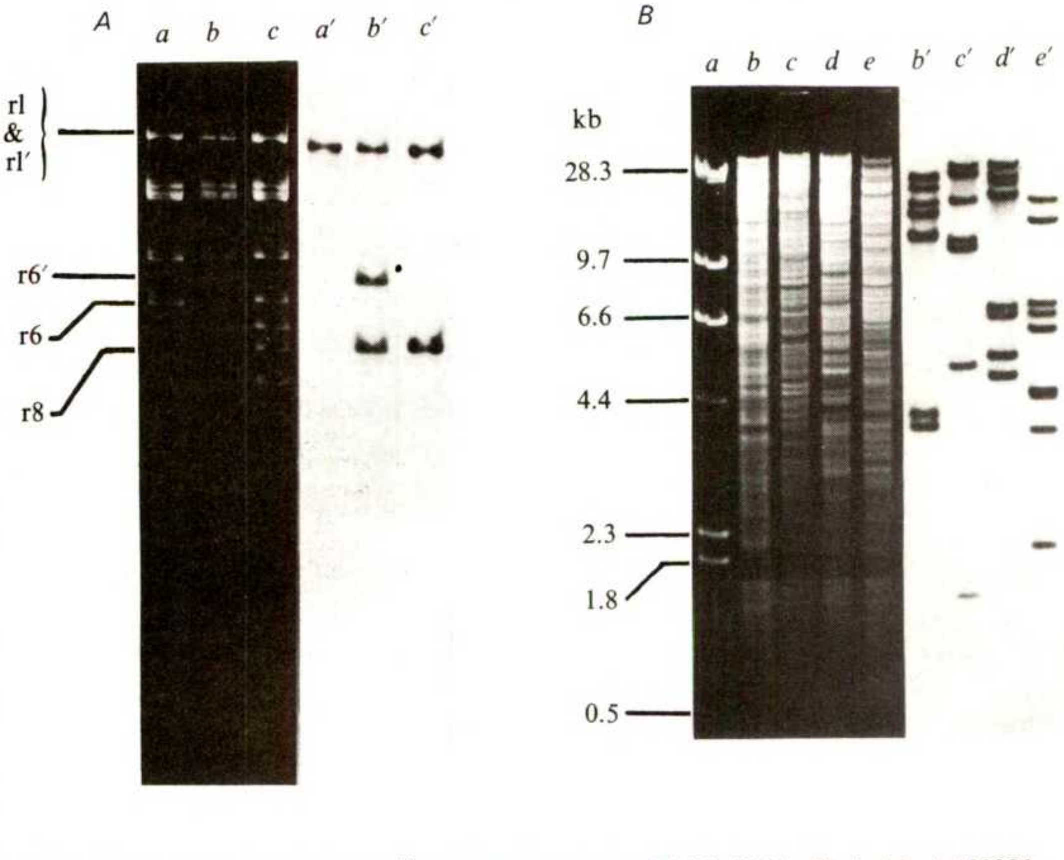

Fig. 2 Ethidium bromide-stained 0.7% agarose gels and autoradiograms of the filter obtained from the gels after hybridization with a [5′-^{32}P]-labelled IS1 DNA probe. *A*, Columns *a*, *b* and *c* are original gels of *Eco*RI digests (~1 μg) of plasmids, RTC, R100-25 and R100, respectively. r1, r6 and r8 are the fragments of R100; r1′ and r6′ are fragments unique to RTC and R100-25, respectively. r1, r8, r1′ and r6′ hybridized to the IS1 probe (β) as shown in columns *a*′, *b*′ and *c*′. *B*, Columns *b–e* are the total DNA (3 μg) of an *E. coli* K12 derivative, JE5519, digested with *Eco*RI, *Hin*dIII, *Bam*HI and *Pst*I, respectively. Column *a* is a *Hin*dIII digest of λ DNA used as length standards (in kilobases (kb))[30]. *b*′–*e*′ Are autoradiograms made after hybridization with the IS1 probe (β). For hybridization, the DNA in the gels was denatured and transferred to a sheet of nitrocellulose filter (Millipore) according to Southern[18]. The filter was then rinsed with 2 × SSC for 20 min, baked at 80 °C for 3 h and wetted from one side with 20 μl cm^{-2} of hybridization medium (50% deionized formamide and 4 × SSC) containing [5′-^{32}P]-labelled IS1 DNA (1.5×10^4 c.p.m. ml^{-1}). Wetted filters were wrapped with Parafilm and incubated in a sealed bag at 42 °C for 18–20 h. After hybridization, the filters were washed twice with 250 ml each of hybridization medium at 42 °C for 1.5 h and four times with 250 ml each of 2 × SSC at room temperature for 10 min, and blotted dry. Kodak X-ray film (SB-5) was used for autoradiography.

of the *Eco*RI digests of the plasmid DNA. The DNA fragments seen in the gel were denatured with alkali and then transferred on to a nitrocellulose filter using the method described by Southern[18]. Figure 2*A* (*a′–c′*) shows an autoradiogram of the filter obtained from the gel shown in Fig. 2*A* (*a–c*) after hybridization with the ^{32}P-labelled probe. The result shows that the *Eco*RI fragments of the plasmids which hybridize with the probe are those containing the IS1 sequences. Any one of the ^{32}P-labelled strands prepared from the three fragments described above gave results identical to those shown in Fig. 2*A* (*a′–c′*).

Table 1 Summary of number of IS1 copies in bacterial strains examined

Strain	Source* (ref.)	No. of IS1 copies
Enterobacteriaceae family

Bacillus subtilis	H. Ohtsubo	0

Species in the family Enterobacteriaceae are grouped into tribes as described in ref. 25. Bacteria in the tribe Escherichieae are more closely related to those in the tribe Klebsielleae than are the other tribes Erwinieae and Proteeae. Within the tribe Escherichieae, *E. coli* species are more closely related to *Shigella* species than are others[21–23]. The pedigree of *E. coli* K12 strains is shown in Fig. 3. The number of IS1 copies in each bacterial strain was estimated from the number of bands seen after hybridization with ^{32}P-labelled IS1 probes to the DNA, which was digested with the restriction endonuclease *Pst*I except in the cases of *S. dysenteriae* and *S. sonnei*, where *Eco*RI or *Hin*dIII was used. w.t., Wild type.

* CGSC; *E. coli* genetic stock centre at Yale University: ATCC; American Type Culture Collection.

† The exact IS1 copy number was difficult to estimate because several of the bands appeared as doublets or more.

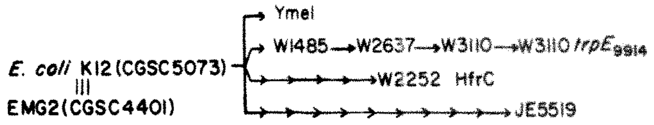

Fig. 3 Pedigree of *E. coli* K12 strains examined. Arrows indicate the number of steps required to introduce genetic markers according to Backman *et al.*[19]; *E. coli* K12 (CGSC5073) and EMG2 (CGSC4401) are supposed to be identical strains.

To determine the number of IS1 copies carried on the chromosomal DNA of *Escherichia coli* K12, total DNA was isolated from the *E. coli* derivative JE5519. Figure 2*B* shows an ethidium bromide-stained gel of the DNA cleaved with *Eco*RI, *Bam*HI, *Hin*dIII and *Pst*I, and an autoradiogram of the filter obtained from the gel after hybridization with a [5′-^{32}P]-labelled IS1 DNA probe. The results show that each enzyme generates distinctive DNA bands hybridizable with the probe. *Pst*I, which cleaves the IS1 sequence once (see Fig. 1*A*), generated the largest number of bands, 10; this is the most realistic estimate of the number of IS1 copies in the chromosome, as *Pst*I will disrupt the linkage of two copies of IS1 if present in the chromosome.

We examined the DNA from *E. coli* K12 derivatives other than JE5519. These derivatives are listed in Table 1 and their pedigree is shown in Fig. 3. Among the derivatives examined, the cells of wild-type *E. coli* K12, W1485 and EMG2 carried an F plasmid. The F plasmid DNA isolated from these strains contained no sequences hybridizable to the IS1 probes (data not shown); therefore, the difference in the number of IS1 copies in these strains is due only to the presence of IS1 in the chromosome. The results of an autoradiogram for some strains (Fig. 4) shows that *Pst*I digests of the DNA from various *E. coli* K12 strains generate not only common bands hybridizable to IS1, but also some bands unique to each strain. For example, a wild-type *E. coli* K12 strain (CGSC5073) shown in Fig. 4 was found to contain eight copies of IS1, whereas the strain EMG2 (CGSC4401), which is also supposed to be a wild-type *E. coli* K12 (ref. 19), contains six IS1 copies and shows the same pattern as that seen in Ymel and W1485. The fact that EMG2, Ymel and W1485 showed the identical pattern of six bands hybridizable with the IS1 probe suggests that this number of copies of IS1 was present in the chromosome of *E. coli* K12 when it was originally isolated from a natural source. All other derivatives contained increased numbers of IS1, demonstrated by the addition of new bands to those seen in EMG2, Ymel and W1485 (see W2637, W3110 *trpE*$_{9914}$, JE5519 in Fig. 4). It is interesting that some bacterial strains, which were identical but kept in different laboratories, contain a different number of copies of IS1.

As shown in Fig. 4, *E. coli* C contains three copies of IS1, whereas *E. coli* W contains no IS1s. This indicates that the distribution of IS1 is unique for each *E. coli* species.

We examined the DNA from various bacteria other than *E. coli*, primarily from the Enterobacteriaceae family (Table 1). As summarized in Table 1, *Klebsiella aerogenes* and *Serratia marcescens* generated one and two DNA bands hybridizable with a [5′-^{32}P]-labelled IS1 probe, respectively, but *Shigella dysenteriae* generated at least 40 bands hybridizable with the probe. None of the other strains examined generated any fragments hybridizable to the IS1 probe. The high copy number of IS1 seen in *S. dysenteriae* DNA is present not only in this species, but also in *Shigella sonnei* and *Shigella flexneri*, although the gel patterns obtained were different from each other. *Shigella boydii*, however, was found to contain only two copies of IS1.

S. dysenteriae SH16 harbours two plasmids 2 and 30 kilobases in length[20]. Hybridization analysis of these plasmids showed that the 30-kilobase plasmid contains one copy of IS1. In *S. sonnei* at least four different plasmids, about 4–7 kilobases long, were present but they contained no copies of IS1. These results indicate that the IS1 sequence seen in these two *Shigella* species are mostly present in the bacterial chromosome. We have not examined whether the other bacterial species harboured plasmids or whether these plasmids, if present, carry IS1 sequences.

A phylogenetic tree of the Enterobactericeae has recently been postulated based on immunological comparison of enzymes[21], comparison of 5S rRNA sequences[22] and comparison of the ribosomal proteins[23] (see Table 1 legend). These relationships correlate well with various other measures of biochemical relatedness, including bulk DNA homology[24], and with the numerical taxonomic groupings[25] of the Enterobacteriaceae. The distribution of IS1 sequences in various bacteria as revealed in the present analysis, however, does not correlate with the taxonomic or phylogenetic relationship of these bacteria. Besides the *E. coli* and *Shigella* strains, we detected the IS1 sequence only in *K. aerogenes* and *S. marcescens. Salmonella typhimurium, Citrobacter freundii* and *Edwardsiella tarda*, which did not contain IS1, are more closely related to *E. coli* or *Shigella* than are *K. aerogenes* or *S. marcescens* (see Table 1 legend). Although *E. aerogenes* belongs to the same tribe, Klebsielleae, as *K. aerogenes* and *S. marcescens*, it did not contain IS1. Furthermore, as described previously, *E. coli* W did not contain IS1 even though all other *E. coli* species examined did so. These results suggest that the lateral transfer of the IS1 element from one bacterial strain to other bacterial strains occurred after these bacteria had diverged phylogenetically. Genetic exchange is known to occur among Enterobacteriaceae using various systems, such as conjugation mediated by plasmids, transduction mediated by bacteriophage and direct DNA transformation. In fact, the resistance plasmids R100, R1 and R6, which are originally from *Shigella*[26] and contain two copies of IS1 (ref. 12), have been transferred to *E. coli* K12 and other bacterial strains by conjugation; the bacteriophage, P1, which can grow in *E. coli* K12 and *Shigella*, contains the IS1 sequence[27] and has been used for genetic manipulation in the *E. coli* K12 system. It is difficult, however, to determine where IS1 originally appeared.

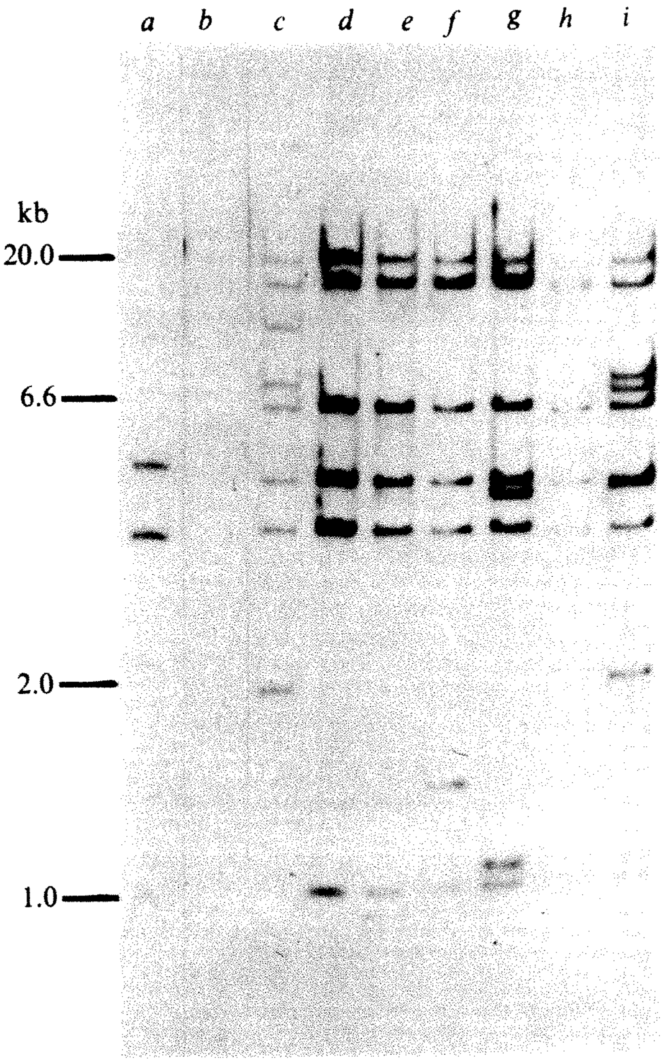

Fig. 4 Autoradiograms after hybridization of a [5'-^{32}P]-labelled IS1 fragment (γ) with *Pst*I fragments of total DNA from different *E. coli* strains: *a, E. coli* C; *b, E. coli* W; *c, E. coli* K12 (CGSC5073); *d, E. coli* K12:Ymel; *e, E. coli* K12:W1485; *f, E. coli* K12:W2637; *g, E. coli* K12:W3110 *trpE*$_{9914}$; *h, E. coli* K12:W3110 (CGSC4474); *i, E. coli* K12:JE5519. *Hin*dIII digests of phage λ DNA were used for calibrating fragment sizes. kb, Kilobases.

It is known that some transposable DNA elements containing resistance genes for antibiotics and enterotoxin genes are flanked by two IS1 sequences[12,14,16,28]. It is known that many resistant bacteria have different resistance spectra due to the presence of various kinds of plasmids, a fact first reported in *Shigella* strains in Japan[26]. This suggests that the elaborate recombination events responsible for the generation of resistance plasmids may have been facilitated by the large number of IS1 sequences in *Shigella*.

In addition to IS1 and several insertion sequences including IS2 and IS3 (see ref. 3), there is a group of translocatable elements responsible for resistance to various antibiotics. The investigation of the presence of these elements will also be important for the elucidation of the origin of resistance plasmids in bacteria.

We thank Monica Riley and Algis Anilionis for the gift of bacterial strains and bacterial DNA, and Jonathan Rosen and Tom Ryder for critical reading of the manuscript. K.N. was supported under the USPHS grant GM19043 (Principal Investigator, M. Inouye). This work was supported by USPHS research grants GM22007 to E.O. and GM26779 to H.O.

BOOK REVIEWS

Cognition at the crossroads

John C. Marshall

Language and Learning: The Debate Between Jean Piaget and Noam Chomsky. Edited by M. Piattelli-Palmarini. Pp.409. (Harvard University Press/Routledge and Kegan Paul: 1980.) $20, £9.75.

IF THIS book did not exist, only a supreme ironist could have invented it.

In 1975 the Royaumont Center for a Science of Man revived an ancient tradition: before a vociferous audience of highly distinguished molecular biologists, anthropologists, mathematicians, psychologists, computer scientists and philosophers, two pre-eminent scholars, Jean Piaget and Noam Chomsky, conducted a disputation on the (biological) nature of the human soul. The only aspect of the debate which is beyond dispute is that the central figures are indeed the two scholars who have had the greatest impact upon the psychological sciences in the second half of this century.

It is ironic, but not altogether surprising, that neither man is a psychologist by training. Piaget began his career in biology and then spent some 50 years observing the development of reasoning in children, much as a naturalist might; Chomsky studied logic, philosophy of science and structural linguistics before noticing, as a graduate student, that the grammars he was writing could be interpreted as theories of language-acquisition.

The second irony, or at least shock, arises from being confronted with such diametrically opposed responses to the command "Etonnez-moi!". Piaget has astonished us with data which, if valid, suggest that children live in a world which is incommensurate with that of their parents. It is not that children merely know fewer facts than we do, but that their entire interpretive framework, their logic, differs from ours. For Piaget, the child believes that water poured from a short, wide glass into a tall narrow one increases in volume; likewise, the child may grant that A is larger than B, and that B is larger than C, but will not endorse the inference that therefore A *must* be larger than C. For the child, the latter claim is an empirical issue to be settled by observation not speculation. Critics of Piaget typically attack the database from which his startling conclusions are drawn: the child misunderstood the question, became confused by the perceptual salience of the array, or forgot the premises before getting around to the answer. As Jacques Mehler points out, the experimentalists' standard retort to Piaget is thus not to explain his results but rather to explain them away.

Camera Press

Jean Piaget — children think differently

Contrariwise, the primary data that Chomsky has drawn attention to are almost trivially plain and unimpeachable. For example: the sentence "We like each other" is, roughly, a paraphrase of "Each of us likes the other." But "We expect John to like each other" does not mean "Each of us expects John to like the other"; indeed the former string is not even a well-formed sentence of English. The facts here and in myriad other cases are not in doubt. Chomsky astonished us by demanding an explanation for such obvious facts. That is, he outlined a program for linguistic theory: to write with a finite number of rules, some of them recursive, a grammar that generated all the sentences of a language and none of the non-sentences; to formulate the rules in such a way that they automatically assign the correct structural description to each generated sentence; to discover the most restricted schematism for rule-types that will allow the description of any natural language while formally excluding rule-types that are found in no natural language. The very idea of such a program was breathtaking and even the admittedly limited success with which Chomsky and other linguists have been able to carry it out is a good deal more impressive than anything else that has been achieved in the human sciences. Chomsky's revolutionary goals rapidly came to define the field and, except in a few benighted backwaters, linguistics now is what Chomsky in 1955 said it should be. "Internal" critiques of Chomsky therefore take just the form one would expect: particular rules and rule-schema are attacked because they overgenerate, undergenerate or otherwise assign incorrect structural descriptions.

The third irony lies in the topic of debate. Piaget has rarely, if ever, studied language. Although the title of his first major publication contains the word "language", Piaget's concern was not how children talk but rather what they talk about. In the opinion of many psychologists, particularly those who follow young children around with tape-recorders, Chomsky has never studied language-acquisition either. Finally, neither Piaget nor Chomsky consider that learning *as classically conceived* plays more than a minor role in the acquisition of any significant body of knowledge.

One might predict then that the Royaumont Center has devised a recipe for disaster, but happily this is not so. All the participants rise magnificently to the occasion and a display of truly virtuoso editing from Massimo Piattelli-Palmarini has converted the proceedings into a first-rate book.

Chomsky's position has a stark simplicity. The adult's linguistic competence can be represented by a generative grammar that pairs sound and meaning correspondences across the infinite number of sentences of the language. This grammar is an abstract description of one component of mind, a theory of the steady-state attained. Universal grammar, by contrast, characterizes the properties that languages hold in common or that constrain the space wherein they may vary. These principles, along with parameters that allow for variation between languages, are attributed to the child's initial state; they form boundary conditions within which the learner attempts to locate the specific grammar of the particular language to which he is exposed. The function of exposure to a particular linguistic environment is to set the parameters left open in universal grammar; does the

Noam Chomsky — universal grammar

language have structure-dependent movement rules (English) or not (Japanese)? Is the order of base elements subject–verb–object (English) or subject–object–verb (German)? Can tensed sentences be overtly subjectless (Italian) or not (English)? Once the value of a parameter has been fixed, the relevant structures then interact with universal principles so that a range of other properties of the language follows deductively. It is in this sense that the child comes to know more than he experiences.

Chomsky's program ascribes to the genotype some highly constrained, domain-specific principles. Thus the pattern of the linguistic examples quoted earlier is interpreted by postulating a condition on rules of sentence grammar such that if an embedded sentence has a subject (*John* in "We expect John to like each other"), only that subject is accessible to the rule of reciprocal interpretation. The effect of the specified subject condition is to force the complement of the ungrammatical string into the anomalous structure "John likes each other". Many of the participants find the imputation outrageous. They concede that radical behaviourism is dead (William of Occam never intended psychologists to cut their throats with his razor) but baulk at attributing the specified subject condition to the genome. Surely general principles of self-regulation, sensori-motor intelligence or learning-strategies will suffice for the child to acquire his language? Each time that one of these suggestions crops up, Chomsky asks for an example of a general learning strategy (or whatever) that would lead to the adult's language obeying the specified subject condition. And each time he does so, the silence is deafening.

Mention of learning inspires Jerry Fodor to essay his now notorious argument that all knowledge is innate (*The Language of Thought*; Harvester, 1975). Fodor observes that the only accounts of "concept learning" ever developed are variants of the theory of inductive inference. A hypothesis ("All emeralds are green") is projected, and if confirmed (= not disconfirmed) by the evidence, belief is fixed. The theory entails that "the concepts that figure in the hypotheses that you come to accept are not only *potentially* accessible to you, but are actually exploited *to mediate the learning*". Inductive inference is normally thought of as the cornerstone of empiricist theories of learning, but, as Fodor concludes, the model "assumes the most radical possible nativism: namely, that any engagement of the organism with its environment has to be mediated by the availability of any concept that can eventually turn up in the organism's beliefs". The upshot is to make innate all the semantic primitives or meaning postulates that characterize every concept from elephants to electrons. They lurk inside the organism waiting to be triggered by the environment. Once more, many of the participants at the symposium are affronted although the ghost of Socrates can be heard cheering from the sidelines. Fodor's argument has circulated widely for five years, and is generally regarded as misconceived. Yet no counter-argument is known nor any convincing alternative account of learning whereby the conclusion can be avoided. Conceptual *development* — the acquisition of qualitatively stronger logics, in Piaget's terms — is not ruled out by Fodor's account, but it must arise from maturation, not "learning".

The metaphor of the growth of mental organs is congenial to both Chomsky and Piaget, though Chomsky takes the stricter line. Piaget has long held the view that an organism can "assimilate" certain structural properties of the environment, thereby allowing learning *sine* learning. The notion has affinities with J. J. Gibson's theory of "direct perception". Piaget's "constructivism" attempts to show how "new operations and structures" can arise from interaction with the environment (and hence undermine Fodor's conclusion). A favourite example of Piaget's is the concept of "reversibility". The idea originates, Piaget believes, when the child notices that he can, for example, pick up a ball, replace it and pick it up again. Expressed first through the operation of "sensori-motor intelligence", the concept of reversibility eventually becomes available for incorporation into more abstract schemata (if $A + B = C$, then $C - B = A$). Piaget, however, fails to show how the concept could arise from sensori-motor play or become generalized *except* in an organism that was specifically pre-adapted to encode its experience in terms of reversibility. We thus return full-circle to Fodor's point.

Piaget tries to reinforce his position by adopting an analogy that the molecular biologists find objectionable. He employs a quasi-Lamarckian account of phenocopies in which the environment can *change* the structure of an organism. This holds little appeal for François Jacob, Antoine Danchin, Jean-Pierre Changeux and Jacques Monod. Jacob stoutly defends neo-Darwinism: phenocopies constitute "only a slight variation within the realm of what the genotype allows"; Danchin stresses how molecular biology has advanced "*without allowing the intervention of even the least instructive notion on the part of the environment*"; and Changeux expounds his elegant theory of synaptic stabilization in which the effect of the sensory environment is simply to select a pattern of connectivity by pruning unused elements.

As Piattelli-Palmarini emphasizes in his superb introduction, the research program of molecular biology, conducted at the level of concrete mechanism, bears a striking resemblance to Chomsky's program, although the latter enterprise only characterizes the "abstract conditions that unknown mechanisms must meet" (Chomsky). Tracing these conditions back to their underlying mechanisms should keep us all busy for many a year. □

Pions and nuclei

D. V. Bugg

Theory of Meson Interactions with Nuclei. By Judah M. Eisenberg and Daniel S. Koltun. Pp.403. (Wiley-Interscience: 1980.) £21.25, $49.95.

NUCLEAR forces are due to exchange of mesons such as the pion. If, in nuclear structure physics at low energy, one gives nucleons a nudge weak compared with these strong forces, a rich excitation spectrum results. The meson factories now allow systematic study of much larger excitations, using beams of pions or nucleons. The scattering is dominated by nucleon excitations such as the Δ (1230) at 300 MeV in the πN system. To make sense of the data, it is necessary (i) to know the fundamental interactions (πN, NN and $N\Delta$ including off-shell extrapolations), and (ii) to solve the many body problem. Since the interactions are strong, it is generally inadequate to approximate the problem by single scattering from individual nucleons.

This book sets out to treat the multiple scattering series in systematic fashion. The exposition is concise, elegant and reasonably transparent, and brings order to the chaos of approximations in the literature. The aim is to educate research workers and students in this immediate field, though students will need some previous exposure to formal scattering theory up to the Lippmann–Schwinger equation. Armed with this and the rather brief exposition of πN dynamics given in the book, they can follow clear trails through the jungle of multiple scattering series (to fourth order, including nuclear excitation and anti-symmetrization), Fadeev equations, dispersion theory, optical models and Glauber approximation to confront data on elastic and inelastic nuclear scattering, knockout reactions, pion absorption and mesic atoms. The formal theoretical machinery is all there, and the precise relationship between exact solutions and approximations is quite clear.

The disappointment of the book is that, after all this effort, little qualitatively new physics emerges. This reflects on the subject, not the presentation. As yet, one does not know whether failures of calculation arise from approximations (necessary to limit computation) or from ignorance of fundamental interactions. This is a pity, since data like these potentially hold the key to understanding Δs in nuclei and nuclear matter at high densities (hence high Fermi levels), where a phase transition to a pion condensate may occur. ☐

D. V. Bugg is Professor of Nuclear Physics at Queen Mary College, University of London, and an SRC Senior Fellow.

Towards harmony in Polar geobotany

Stanwyn G. Shetler

The Arctic and Antarctic: Their Division into Geobotanical Areas. By V.D. Aleksandrova. Pp.247. (Cambridge University Press: 1980.) £15, $34.50.

AT LAST an attempt has been made at reviewing the literature on the vegetation cover of both the Arctic and the Antarctic and also at classifying all Polar geobotanical areas from a single point of view. Such an extraordinary synthesis is the more important for coming from the eminent Soviet geobotanist, Vera Aleksandrova. One of the world's foremost authorities, she has been a leading figure in ecology for nearly three decades in the country with the lion's share of the Arctic.

Aleksandrova's contribution, now translated from Russian, should do much to bridge the gap between Soviet and other Polar ecologists. Apart from the formidable language barrier, there are fundamentally different traditions in concept and method; even the very terms are different.

Soviet geobotanists, in the traditional European mould, continue to classify vegetation as an end, a science, in itself. This book is fine testimony to the continuing preoccupation of the Soviet school of geobotany with discovering the ultimate phylogenetic ("phylocoenogenetic") hierarchy of plant communities. Western, particularly North American, ecologists largely have taken a much more pragmatic approach. Classification is a means to an end, a means of organizing the state of knowledge of vegetation.

Aleksandrova's objectives, to subdivide and classify the geobotanical areas of Polar lands and at the same time to summarize succinctly the vast amount of data on vegetation cover, have been met well. Interesting and potentially useful as her classification is, her vegetation summary is certain to prove the more valuable to botanists generally, who until now have not had a single place to turn for such a detailed and yet generalized overview of the vegetation cover in the Soviet Arctic. Thus her bias toward greater detail and precision for Soviet territory is easily forgiven. We can be grateful that the basis did not exist for casting her study in the mould of some recondite phytosociological system of classification with its pointless nomenclature, even though she would not agree.

She divides the Arctic into the Tundra Region and Polar Desert Region. The first is further subdivided into two subregions: Arctic Tundras and Subarctic Tundras, differentiated mainly by the presence of shrubby birches (*Betula*) in the zonal associations of the latter but not the former. Both are further subdivided into provinces, subprovinces and districts. The Antarctic is divided into the Subantarctic Cushion Plant Region and the Antarctic Polar Desert Region. The latter is an analogue of the Arctic Polar Desert Region, but she finds no South Polar tundra analogue.

Her system of classification might be termed holistic for drawing on such a broad range of data. Two types of features are used: diagnostic and characterizing. The diagnostic features are zonal features that govern the delimitation of the major geobotanical areas. Ultimately, however, Aleksandrova, like geobotanists in general, must place strong reliance on floristics, little else being as tangible and objective. Certain species (*Salix polaris*, for example) do yeoman service in the characterizations.

Despite its small size, the book is rich in detail, perhaps too much so in places. This detail and the liberal use of phytosociological jargon do not make for light reading; it is clearly a book to refer to, not to read straight through. The book would have benefited enormously from some well-chosen photographs of the main types of vegetation discussed. A bit too much geography, especially of the USSR, is taken for granted, and the reader wishes for a good map of the Arctic with major place names shown. A glossary of terms used in Soviet ecology would also be most useful.

The book is well produced with a minimum of errors, all minor. The extensive bibliography is invaluable. With few exceptions it seems amazingly complete for North America (Raup's work on the Mackenzie Territory seems to have escaped review). As translator, Doris Löve has done a remarkable job, and she is to be commended for undertaking this task on behalf of all of us.

Criticisms notwithstanding, this is an outstanding piece of work that will go far toward fostering understanding and harmony in Polar geobotanical research, while at the same time laying foundations for new efforts. This instantly indispensable reference is sure to become a classic. ☐

Stanwyn G. Shetler is Associate Curator in the Department of Botany, Smithsonian Institution, Washington DC.

TAS, 45 years on

M.J. Seaton

Atomic Structure. By E.U. Condon and Halis Odabaşi. Pp.658. (Cambridge University Press: 1980.) Hbk £30, $83.50; pbk £9.95, $26.

The Theory of Atomic Spectra by Condon and Shortley, published in 1935 and familiarly known as TAS, is one of the great scholarly classics of twentieth-century scientific literature; it was reprinted many times by Cambridge University Press but there was never a second edition. From 1962, when he went to the University of Colorado, until near the time of his death in 1974, Ed Condon worked on a new book in collaboration with Halis Odabaşi who is now at Boğaziçi University, Turkey. I witnessed the work in progress on the tenth floor of the JILA tower; its fruits have now been prepared for publication by Odabaşi with assistance from many people, particularly John Cooper and Roy Garstang, and published as *Atomic Structure*.

We can cherish the treasures in an unfinished symphony without concealing the shortcomings of the work as a whole. For me the main source of delight in this new book is the first chapter, concerned with the historical developments which culminated in the modern formulation of quantum mechanics. Others may find particular merit in the chapters on group theory (of this subject, it was said in the introduction to TAS that "We manage to get along without it"). *Atomic Structure* is concerned exclusively with the non-relativistic theory, although, in his preface, Odabaşi tells us that he and Garstang are working on another volume, intended as a sequel, in which the relativistic theory will be discussed. The main new developments in non-relativistic atomic structure physics since TAS was published are the introduction of Racah algebra techniques, the carrying out of much more accurate calculations using computers and the accumulation of a wealth of new experimental data. Of these, a chapter is devoted to the first but the other two are sadly neglected. Much of the book is concerned with the central-field model, in particular the calculation of the algebraic coefficients which occur in the diagonal matrix elements of the Hamiltonian using a single-configuration representation. Having obtained such coefficients, Condon and Shortley in TAS immediately consider whether "the formulas agree with the data in any sense". Their first confrontation is for the configuration p^2, for which the single-configuration theory tells us that there are three terms, ^3P, ^1D and ^1S, and gives us a predicted ratio of separations

$$[E(^1S)-E(^1D)]/[E(^1D)-E(^3P)] = 1.5$$

this ratio being determined entirely by the algebraic coefficients and independent of the choice of orbital functions. The comparison with experimental ratios given in TAS, 1.13 for C I, 1.14 for N II, 1.14 for O III and so on, shows the inherent limitations of the single-configuration theory, which may give useful information on the relative positions of the terms but fails to give precise quantitative information on energy levels and other properties of atoms. While many similar comparisons were given in TAS, only a limited number are given in *Atomic Structure*, and these only in a concluding chapter and in the context of Hartree–Fock theory. The inherent limitations of the single-configuration theory are thus obscured, and a large amount of more recent work, using multi-configuration methods, is neglected completely. (In such work, the entire problem is handled on a computer — the algebra, the calculation of radial functions, the diagonalization of the Hamiltonian matrix and the computation of matrix elements required for the determination of other atomic properties.)

Advances in studies of atomic spectra and atomic structure which have taken place during the past 45 years are such that it becomes increasingly difficult to describe them in a single comprehensive book. A number of specialist works have been published, and doubtless others will appear, but the need for a more comprehensive work remains. Although *Atomic Structure* fails to meet this need satisfactorily, it contains much that is of value. Professor Odabaşi, others who have assisted and Cambridge University Press should be thanked and congratulated for having made it available to us. □

Tool use — fundamentals and philosophy

Toshisada Nishida

Animal Tool Behavior: The Use and Manufacture of Tools by Animals. By Benjamin B. Beck. Pp.307. (Garland: New York, 1980.) $24.50.

THE biggest difficulty in studying tool-using behaviour is deciding what constitutes tool use and what does not — no two scientists would completely agree with any definition. Beck illustrates this fundamental problem right at the beginning of his book in providing a test for the reader. He presents 50 animal behaviours from which those representing tool use must be chosen — I only just passed, answering 35 correctly.

The author goes on to catalogue, in considerable detail, observed tool behaviour, and provides a useful classification of tool-manufacture into four components: *detach, subtract, add or combine* and *reshape*. There are a few omissions and some examples with which I would disagree — fishing probes made of the mid-rib of leaves may be an overlooked example of *subtract* and chimpanzees do not "dip" but rather fish for *Camponotus* ants. Beck then reconsiders his catalogue according to the major functions of tool use: *to extend the user's reach, to amplify mechanical force, to augment agonistic display* and *to allow more effective control of fluids*. Again this is a useful categorization, but I would prefer to substitute "augment signal value of display" for "augment agonistic display" as chimpanzees have been seen to use tools even in courtship and other non-aggressive displays.

How do animals begin to use tools? Beck stresses that the discovery of novel tool-using patterns could result fortuitously from exploratory object manipulation and reviews the factors that influence the development of tool use: maturation, and associative and early experience. He then goes on to criticize Alcock's view that tool-users are morphologically ill-adapted to compete for resources and that tool-use compensates for lack of biological equipment. Since all behaviour can be viewed as compensating for lack of morphological structure, the author argues that Alcock's tenet has no special significance for the evolution of tool-using behaviour. Taking chimpanzees as an example, he also persuasively argues against another thesis of Alcock's: that tool-users have invaded niches that are not at all characteristic of their phylogenetic group.

In considering the cognitive aspects of tool use, Beck questions whether the behaviour can be called "intelligent". Pointing out that non-tool behaviour of herring gulls (shell-dropping) and chimpanzees' tool behaviour (termiting) share cognitive similarites, he attacks the notion that tool behaviour necessitates a cognitive sophistication which is unique and more advanced than that subserving non-tool behaviour. He concludes that there is no unique, orderly relationship between tool use and intelligence, and that social and feeding behaviours are probably far more important factors in the evolution of intelligence. Similar arguments are put forward in reviewing the development of human intelligence and tool use.

Finally, he turns to the philosophical implications of his work in remarking that "tool behaviour should not only be stripped of its role as a primary shaper of our own species, but should also be recast as the progenitor of the engine of our destruction". This pessimism represents a trend stemming from the author's opposition to the ethnocentrism of civilizations and the anthropocentrism of our own species, one which has perhaps been greatly influenced by his anxiety about the future of an Earth under threat from a number of human activities. I don't support all of his remarks. I think that the primary shaper of our species is socio-economic behaviour (including subsistence tool use) and that communicative behaviour is secondary. Moreover, the lack of meaningful relationships between tools and intelligence in other species does not necessarily negate its possibility in *Homo*. In this context, I do not understand why he omits Penfield and Rasmussen's famous contribution to cerebral physiology: hand areas of both motor and sensory cortex in human beings are relatively much larger than corresponding areas in apes and monkeys. This can be easily understood by assuming that tools were one of the major selective agencies in human evolution. Indeed, one of the faults of the book is the lack of a systematic review of gripping organs, grasping methods, handedness and skills in primate tool-use.

Yet this is a stimulating book, rich in suggestions, and undoubtedly the best sourcebook available on animal tool behaviour. □

Toshisada Nishida is a Lecturer in the Department of Anthropology at The University of Tokyo.

ANNOUNCEMENTS

Awards

The 1980 Smith Kline & French Foundation biennial prize for research in clinical pharmacology has been awarded to **Dr M. L'E Orme** (Liverpool University) for his work on oral contraceptive steroids.

The Fyssen Foundation is to award fellowships for the training and support of research fields as ethology, palaeontology, archaeology, anthropology, psychology, logic and the neurosciences. Priority will be given to French scientists wishing to work abroad and to foreign scientists wishing to work in French laboratories. Study grants will normally be granted for one year but may be extended up to three. Applications to the Secretariat of the Foundation, 194, rue de Rivoli, 75001 Paris, France before 1 May 1981. Nominations for the 1981 Prize of the Fyssen Foundation should be submitted to the above address before 1 September 1981.

Young people under 31 working in industry and the universities, are invited to enter for the Suttle Award of the Filtration Society. The award is to be given for the best paper on filtration/separation published between June 1979 and June 1981. Full details from: the Hon. Secretary, The Filtration Society, 2 Woodstock Road, Croydon, Surrey, UK).

Appointments

The Public Health Laboratory Service Board has appointed **Dr J. E. M Whitehead** as director of the Service in succession to Sir Robert Williams who will retire on 1 July 1981.

Dr M. Margaret Clark, has been elected president of the American Anthropological Association.

Dr Gordon Leedale, has been appointed by the University of Leeds to a personal Chair in botany.

Meetings

12-13 March, **Animal Models in Parisitology,** London (C.V. Clark, MRC Laboratory Animals Centre, Woodmansterne Rd, Carshalton, Surrey, UK).

6-12 March, **Nitrogen Recycling in Ecosystems in Latin America and the Carribean,** Colombia (T. Rosswall, SCOPE/UNEP International Nitrogen Unit, The Royal Swedish Academy of Sciences, S-104 05 Stockholm, Sweden).

17-20 March, **Guidelines for Control of Toxic and other Hazardous Wastes,** Wiesbaden (WHO, 8 Scherfigsvej, DK-2100 Copenhagen O, Denmark).

18 March, **Polar Ice and Climate,** London (Royal Meteorological Society, James Glashier House, Grenville Place, Bracknell, Berks, UK).

16-17 March, **Research on Local Wind Environments,** Cambridge (The Institute of Mathematics and its Applications, Maitlanf House, Warrior Square, Southend-on-Sea, Essex, UK).

31 March — 2 April, **Occupational Hazards of the Health Professions,** Homburg (WHO, 8 Scherfigsvej, DK-2100 Copenhagen O, Denmark).

8-13 March, **Structure and DNA–Protein Interactions of Replication Origins,** Salt Lake City, ICN–UCLA Symposia, Molecular Biology Institute, University of California, Los Angeles, California 90024).

8-13 March, **Genetic Variarion among Influenza Viruses,** Salt Lake City, (ICN–UCLA Symposia, Molecular Biology Institute, University of California, Los Angeles, California 90024).

15-20 March, **Developmental Biology using Purified Genes,** Keystone (ICN–UCLA Symposia, Molecular Biology Institute, University of California, Los Angeles, California 90024).

18-19 March. **Information Society: How to cope with the Electronic Revolution,** Rotterdam (Information Dept TNO, PO Box 297, 2501 BD The Hague, The Netherlands).

19-20 March, **Fouling of Heat Exchangers,** Birmingham (Institution of Chemical Engineers, 12 Gayfere St, London SW1, UK).

20 March, **Bracken in Scotland,** Edinburgh (The Meetings Secretary, The Royal Society of Edinburgh, 22, 24 George St, Edinburgh, UK).

23-24 March. **Ion Exchange Technology,** London (Institution of Chemical Engineers, 12 Gayfere St, London SW1, UK).

23-27 March, **Medicinal Chemistry,** Nottingham (Miss L. Hart, Royal Society of Chemistry, 30 Russell Square, London WC1, UK).

24 March, **Applications of Thermal Methods of Analyses in the Pharmaceutical Industry,** Nottingham (Dr D.J.W. Grant, Dept of Pharmacy, University Park, Nottingham, UK).

Employment, training and opportunity

Economic recessions, painful though they may be, are supposed in the conventional wisdom also to be opportunities for industrial change. Industries whose competitiveness has been undermined close factories, throw workers into the dole queues and perhaps go out of business. In due course, the theory goes, some of the people thus displaced from work become the entrepreneurs who found new kinds of industries; others learn new skills so that when the economy revives they too can join the workforce in a new pattern of industry. Adversity, the textbooks say, can thus be an instrument of rapid change. So does it follow that the wave of recession now sweeping the industrialized West is merely a sign of better things to come? Not if Britain is an example, or if the British government's capacity to make the best of the opportunities now presented is typified by its shabby performance in the debate on industrial training in the House of Commons last week.

Nobody disputes the severity of the recession now afflicting the British economy. Manufacturing output has declined by some 15 per cent since its peak two years ago. Employment in the private sector has declined even faster (which promises increased productivity when the worst is over). Unemployment now exceeds 2.5 million, is most serious among young people and threatens to go on increasing at least until the summer. So is this not a splendid opportunity for making sure that the people out of work are well prepared for the recovery that may yet come? Or at least for giving them incentives to acquire new skills if they are so inclined? Both the government and the Labour opposition seem to agree, if last week's debate is to be taken seriously. Their good intentions are not matched by an imaginative appraisal of what should be done.

The narrow issue that divides them is the future of the network of industrial training boards, first set up in 1964 and financed by means of a levy on the turnover of all companies operating in specified groups of industries. The system is not as onerous as it may seem. Intelligent companies ensure that they recover at least as much in financial support for their internal training operations as they pay by way of levy. Some of the best apprentice schools in Britain are now financed by means of this genteel laundering of money, and the system may also blunt the edge of the longstanding discontent of progressive companies that much of the training they provide eventually benefits less farsighted competitors which pick up skilled men in the job market. The system of training boards has probably also served a useful purpose in industries such as catering, where individual companies tend to be small and where the labour force is mobile. The system, nevertheless, has serious weaknesses. From the start, the training boards have been inclined to impose on the industries they supposedly serve patterns of training whose utility is disputable. Since 1973, when the administration costs of the training boards became a charge on the central government, the boards have become even more bureaucratic than they were before, and extravagant to boot. (At least one director of a training board is paid more than a university vice-chancellor at a British university.)

For several months, it has been clear that this state of affairs could not continue. Even the agencies of the British government sympathetic to the training boards (the Manpower Services Commission, for example) have acknowledged that the system has serious faults. Industrial companies, especially progressive companies, have become increasingly discontented with the arrangements. A few months ago, the Conservative Party's Centre for Policy Studies advocated the simple abolition of the training boards. The Conservative government, as much concerned with the cost of keeping the boards in being (more than £50 million a year) as with the need for training, has resolved to transfer the cost of administration back to the industries which contribute to the boards. The case for this course of action, put forward in the House of Commons last week, is that a transfer of full responsibility for the boards back to the industries concerned would provide a built-in assurance that industrial training is geared to industrial needs.

The argument, so far as it goes, makes sense. It is, however, disingenuous to suppose that there will be no consequential changes. Many industries now saddled, as they see it, with training boards will regard the Employment and Training Bill now working its way through the House of Commons as a licence to do away with their training boards. In many cases, the result would be far from tragic. Many of the complaints recently levelled at the boards are fair. One serious weakness is that there has never been an objective evaluation of the educational value of their training schemes. A more serious weakness is structural. If the best outcome of the present recession of the British economy is the emergence of entirely novel industries, what purpose can be served in perpetuating a pattern of training geared to industries in decline? Although true, none of it excuses the narrowness of the British government's case for change.

Everybody accepts that this point in the current business cycle calls for new initiatives in training. The British government's argument that the responsibility should as a matter of principle fall squarely on industry is, however, profoundly flawed. Progressive industrial companies have always acknowledged that their own self-interest requires some investment in the skills of their own workpeople, and will continue to do so. Most of them acknowledge that the cost is worthwhile, even if some of their skilled people eventually work for competing companies. But the same industrial companies have no interest in providing their workpeople with skills suited to entirely novel industries. The result is that people working in, say, traditional mechanical engineering are unlikely to be given the chance, within their own organizations, of becoming skilled in electronic engineering or computing. And what of those who are out of work, and thus outside the scope of the industrial training boards? In Britain, in the past few years, the Manpower Services Commission has done some useful work in keeping young people off the streets and providing them with modest skills, but none of this amounts to the creation of the body of skill on which an entirely novel pattern of industry might be built some years from now.

One paradox is that a government devoted, so far as can be told from its public declarations, to individual initiative should so overlook what is now the obvious need — that people by their individual decisions should more easily be able to acquire the skills they consider would help them to make their way in the brave new world ahead. Another paradox is that there is no shortage of facilities for the provision of training, and, by all accounts, no shortage of people seeking skills. Both the universities and the polytechnics are at present short of students and, faced with declining support for conventional students' education, more eager than ever to provide vocational training of various kinds. So why does not the potential demand for advanced training more fully meet the potential supply? At least one part of the explanation is the cost. Those in jobs must pay the full cost of a training course on which they embark out of their taxed income. Those out of jobs are usually unable to raise the

0028-0836/81/080619-02$01.00

fees at all. The implications are plain. If the British government means what it says about the importance of training for the future health of British industry, it must make the cost of training fees paid out of a taxpayer's pocket tax-deductible. And it must use some of the £50 million a year it will save on the industrial training boards to help those out of work to acquire new skills.

In the past two years, the British government has been outwardly resolute in sticking to the monetarist guns that have made the present recession the painful phenomenon it is. The government has been alternatively praised for courage and pilloried for pigheadedness. In reality, it has followed an intermediate course — nationalized industries such as British Leyland and British Steel have been saved from collapse by taxpayers' money. Universities and other institutions of higher education have been exposed more directly to the cold winds of economic change, and like many parts of British manufacturing industry, are running well below capacity. They too will emerge transformed from the present slump. One possible and desirable outcome would be that at least some of them should be more directly involved with continuing education. If the government means what it has been saying these past several months about the importance of retraining and about its respect (or at least lack of enmity) for higher education, and because the falling inflation rate suggests that the time is fast approaching when reflationary policies will again be necessary, it will be absurd if this opportunity is let slip.

How to make dreams untrue

Although the hunt for the philosopher's stone has long since been abandoned, the hunt for its antidote, the material that turns everything into lead, continues apace, most successfully in the dealings between the British government and the nationalized industries for which it is responsible. This is the chief lesson to be drawn from the report of the House of Commons Select Committee on Energy (see page 621) on the new British nuclear energy programme. The committee plainly found its inquiry into the rights an wrongs of the proposal and infuriating experience. The British government chose not to pass on to the committee the advice provided by the Central Policy Review Staffs on the wisdom of building two reactors of the advanced gas-cooled type, thus confirming the widespread understanding that the advice was hostile to the project — and the belief that when British governments extol the benefits of open government, they are thinking of governments other than themselves. The Department of Energy, ostensibly in charge of the substantial commitment of resources entailed by the nuclear programme, is convicted of incompetence by its evidence in the House of Commons. The Central Electricity Generating Board, the nationalized electricity utility which is the constructor and operator of nuclear plants south of the Scottish border, is accused not of excusable incompetence but of unforgivable deviousness. When all the dust has settled, the chief casualty of the committee's forthright report will be the British nuclear programme, fanned to life only in 1979 from the embers of a decade's neglect.

Even after due allowance is made for the way in which select committees these days have to shout to be heard above the reports that flood from their competitors, the language used by the Select Committee on Energy will surprise many of those at whom the complaints are levelled. For the committee's chairman and deputy chairman are both members of the now defunct Select Committee on Science and Technology which, over the years, has been one of the most consistent cheerleaders for nuclear power in Britain. What has gone wrong, the luckless targets of the report will be asking? The answer is that they have compromised a good cause by arrogance, fecklessness (which is a synonym for conscious laziness) and a failure to understand what they are for. In the short run, only they may suffer. Further ahead, taxpayers (and electricity consumers) will also be the losers.

The problem of nuclear power in Britain is by now a problem in national mythology. Ever since the Tizard mission to Washington in 1941, the popular belief in Britain has been that nuclear fission was invented ("discovered" is too passive a word) in the land of Newton. The Ottawa Agreement in 1944 merely codified what most people knew, for which reason it followed as night does day that there should be a truly British nuclear explosion (in 1948) and, now, a nuclear deterrent (called Trident) whose design may be American but whose construction is beyond question British. The commercial exploitation of nuclear power in the past quarter of a century has been a cross between a fairy story and a nightmare. From time to time, radical innovations of technology have been announced, have been widely advertised to an unsuspecting press and then have been allowed to run into the sand because nobody cared about them in the sense of knowing that not merely his reputation but his pension (index-linked) would depend on the realization of his promises to the public. To everybody's surprise, however, the nuclear reactors built in the first heady days of the nuclear enterprise (with natural uranium as fuel and graphite as a moderator) are mostly still working well and helping to reduce the price paid by electricity consumers.

The select committee's forgivable irritation has plainly led it to complain most vociferously at those who sought unsuccessfully to mislead it — the Central Electricity Generating Board is the worst offender. The issue, the committee says, is whether the board can possibly be right in pretending that the nuclear power stations it plans to order in the coming decade will be economical devices for generating electricity when there is so much evidence that the board's assumptions are either untested or untestable. All kinds of questions arise. Can the board be right in guessing that the cost of producing coal (the obvious alternative to uranium) will increase by between 2.5 and 3 per cent a year in the foreseeable future? Can it be believed in quoting capital costs for building the simplest structures when it has so mismanaged the oil-fired power station still painfully half complete on the south bank of the Thames Estuary? Is it, indeed, possible to consider seriously the figures produced by the board and others, purporting to quote future electricity generating costs, if none of the interested parties turns a hair when it turns out that the estimates are wrong, and that the consumers of electricity must pay the difference? For all its rhetoric, the committee would have had a more telling case if it had been able to specify the premises on which utilities (such as the Central Electricity Generating Board) might set out to calculate the future cost of electricity. The truth is, of course, that in the real world there are none that carry conviction. What happens if there is, in the end, a war in the Middle East? It would be too late, then, to call the committee back into session.

With luck, such a drastic course will not be necessary. The committee has done what it needs to do for the decade ahead. It has thrown a spanner in works that were not working. The recommendation that the United Kingdom Atomic Energy Authority should be the chief agent of technological change in the nuclear industry, concerned principally with fast reactors and with fusion, is to be welcomed. The plea that the Department of Energy should somehow equip itself to understand the policies with which it pretends to grapple is right, but will quickly be forgotten with the connivance of the department. The crux of the issue, with which even this loudspoken committee has not come to grips, is that there is no mechanism in the present arrangement for the sponsorship of nuclear or any other kind of power that will allow that the consumer of the electricity should be king. The present British government has widely advertised its wish to reduce the public sector's borrowing requirement by inducing private investors to share some of the risk. Is it not time that it sold the Central Electricity Generating Board to somebody with a long purse — or better still, a conscience? The committee's irritation has led it correctly to pillory the board. It should go on to define criteria by which all such boards should measure their duty.

More secrecy on cryptography research

US academics lean towards self-restraint

Washington

Mathematicians and computer scientists in the United States will soon be asked voluntarily to submit papers on cryptography and related research to the National Security Agency before publication, to see if the agency feels they contain anything that should be kept secret.

This precedent-setting system of self-censorship is being proposed by a study group set up last year by the American Council on Education to look at the growing conflict between national security and academic freedom in cryptography research.

The proposal is something of a compromise between the Defense Department's demands for strict legislation to control the publication of research results with potential security implications, and critics who argue that there should be no restriction on the publication of non-classified research.

However, several scientists warned last week that such voluntary self-regulation could lead eventually to demands for a similar approach to research ranging from lasers to integrated circuits.

Tensions between the Defense Department's security agency and sectors of the research community have grown steadily over the past few years. They stem partly from a desire by the agency to limit the spread of knowledge about virtually unbreakable codes — and the insistence of mathematicians that since many difficult mathematical problems can provide the basis for such codes, any restrictions would have a "chilling" effect on research.

Vice-Admiral Bobby Inman, director of the National Security Agency, has argued fiercely that the free publication of research results could inhibit the agency's data-gathering capabilities. Scientists reply that the codes also have important civilian applications — such as the protection of computer data — that justify their wide dissemination.

Last year these tensions rose to the surface when a computer scientist at Massachusetts Institute of Technology, Dr Leonard Adelman, found a grant application to the National Science Foundation had been passed to the National Security Agency. The agency subsequently offered to support part of his research — but on terms which would have given it the right to determine how much should be published.

The incident caused considerable embarrassment to the National Science Foundation — which protested that it had been seeking the views of the security agency on cryptography research applications for several years. It also pointed out that potential conflicts were being studied by the study group of the American Council on Education, set up at the suggestion of the National Security Agency to discuss ways of controlling the distribution of research results acceptable to the scientific community.

After a year's study, the group agreed at a meeting in Washington last week to propose a system leaving responsibility in the hands of scientists and journal editors by setting up a voluntary review system by the security agency.

According to the group's proposals, soon to be circulated in the scientific community, either a scientist or an editor could submit a paper to the agency for comments on whether it contains information considered to be a threat to national security.

If the agency had no objection, the scientist would be free to publish. If it did object, then the scientist could decide not to publish, proceed with publication against National Security Agency advice — or refer the matter to an independent, five-person committee. This would have two individuals named by the security agency, and three picked by the President's science adviser from a list submitted by the National Academy of Sciences.

In principle, officials of the American Council on Education hope that voluntary self-regulation — which would be introduced for a trial period — would avoid the difficulties of new legislation (which could run into constitutional problems over freedom of expression) while meeting the security agency's main concerns.

In practice, getting the system to work will not be easy. The first step will be for the security agency to prepare a guide to the type of research projects it would expect to evaluate. If the list is too broad, agency officials admit they could end up stifling research unnecessarily; yet if it is too narrow, they fear both that they might tip off others about their principal interests, and miss potentially valuable research findings.

There is also likely to be considerable resistance from the scientific community. Only one of the study group's nine members voted against the proposal for self-censorship; this was Dr George Davida of Georgia Institute of Technology, who found a patent application intercepted by the National Security Agency three years ago, and subsequently received a letter threatening consequences if he discussed his research with his colleagues.

Several academics, however, are worried that self-regulation would create a new category of secret research, pointing out that classified research is now banned on many campuses following the anti-war demonstrations of the 1960s.

The study group's proposals are therefore likely to generate considerable heat. But the political tide is now running in its favour and those who protest at the encroachment of security agencies on individual liberties have fewer friends in Congress than in the past. Vice-Admiral Inman has been nominated as deputy director of the Central Intelligence Agency — and remains committed to the desirability of strong government controls over potentially sensitive research.

David Dickson

Committee douches nuclear energy

The British government's 1979 statement on nuclear power, like its predecessors, is a muddle. This is the opinion of the House of Commons Select Committee on Energy, published this week. The committee asks that decisions to build nuclear plants in the 1980s and 1990s should be decided on their merits and not as part of a planned programme.

On economic grounds, the committee is sceptical about the government's programme to build 15 GW of new nuclear plant by 1992. The Central Electricity Generating Board (CEGB) comes in for particularly sharp criticism. The report cites several instances where the board's evidence on costs was misleading. It criticizes the board for basing future costs on early Magnox plants without acknowledging the effects of subsequent inflation on future capital investment, and for comparing the costs of electricity generated by different types of plant by using "highly uncertain variables" such as the average load factor of plant and future fuel and fuel cycle costs.

Most damning is the complaint that the CEGB presented international cost comparisons suggesting that a pressurized water reactor (PWR) would cost 34 per cent more to build in Britain than elsewhere. The committee says that the generating board's estimate of PWR costs are "too perfunctory" and that it is too tolerant of inefficiencies in the British construction industry. Planning permission for the first PWR plant is still to be sought. Subsequent plants will be either PWR or AGR (advanced gas-cooled reactor) depending on cost and performance.

The committee also suggests that the size of the British programme could be cut if CEGB and the South of Scotland Electricity Board reduced their planning margins for the excess capacity needed for plant failure in particularly severe winters. These have crept up to 28 and 73 per cent respectively from about 17 per cent in the

0028-0836/81/080621-02$01.00

fifteen years ago.

The electricity generating boards are not the only organizations to be criticized in the report, however. Criticisms of the Nuclear Installations Inspectorate, the independent body responsible for nuclear safety, made in Parliament last year, is reiterated. The inspectorate needs to put more effort into assessing the PWR, a design new to Britain, says the committee. Two aspects of PWR design, the integrity of the pressure vessel and problems of two phase flow in the water coolant, call for highly specialized inspectors which the inspectorate lacks. The committee recommends that the inspectorate takes on an ultrasonics expert for testing pressure vessels and that the government remedies, by means of legislation if necessary, the inspectorate's difficulty in attracting suitably qualified staff because of uncompetitive salaries.

The UK Atomic Energy Authority (UKAEA) is criticized for past bad advice to government. The committee recommends that its role as adviser to government on nuclear policy be given to the Chief Scientist's office at the Department of Energy. The UKAEA, it says, should confine itself to research on future nuclear options such as the fast breeder reactor and fusion.

One example, in the committee's opinion, was the recommendation not to consider the Canadian CANDU reactor as a possible option. The committee clearly believes that the CANDU reactor offers certain advantages over both the AGR and the PWR but realizes that the government is too committed to its present plan for an about-turn now. Instead, it asks for a study of CANDU before a final commitment to the PWR is made. **Judy Redfearn**

European Community

Research compared

Brussels

The European Community seems to have taken fright at the gap between Europe and the United States and Japan in spending on research and development. In his first speech to the European Parliament last week, the president of the European Commission, Gaston Thorn, said that in 1981 the Commission will give priority to research and development that will improve the Community's competitiveness with Japan and the United States. The latest assessment of research spending shows that in Europe as a whole, research and development expenditure accounts for 1.9 per cent of Gross Domestic Product, compared with 2.3 per cent in the United States and 2.0 per cent in Japan. If defence research is excluded, the figures are 1.7 per cent, 1.7 per cent and 2.0 per cent, indicating Japan's present dominance by this yardstick.

What, asked Vincent Ansquer, a French member of the European Parliament, can the Commission do? The answer seems to be that the Commission will hope to increase its own research spending in the next few years from 1.6 per cent to 2.0 per cent of the combined research and development budgets of the member states.

Constitutionally, the Commission is less able to influence national expenditure directly but is working on a series of studies which are to be summarized as guidelines for a common research and development policy due to be presented at the Council of Ministers in June this year.

Community research and development expenditure is assessed each year in a report by the Scientific and Technical Research Committee (CREST). Comparisons between member states have been quite influential in the past; for example, they prompted the French government to make substantial increases in its research budget in both 1979 and 1981. The latest report, still being finalized, will say that between 1979 and 1980, member governments' expenditure on research grew in real terms by at most 0.4 per cent.

During the whole of the 1970s, it is now clear, growth rates were highest in West Germany, Ireland and the Netherlands, with France, Italy and the United Kingdom below average. In 1980, Italy emerged at the top of the growth table, with an increase of 20 per cent in real terms of its research and development budget.

The CREST report uses information about the objectives of government expenditure in 1970–79 to infer changing priorities. Throughout the Community, government support for "the general promotion of knowledge", still the largest item, is declining. In stark contrast to government declarations, however, European governments seem to have allowed research contributing to industrial productivity and technological development to fall proportionally.

Increased proportions of national budgets have been spent on the exploration of the Earth and the atmosphere, the planning of the human environment and the protection and improvement of human health. The widely acknowledged need to reduce European dependence on imported energy seems not to have received its due — over the 1970s, real expenditure increased by a mere 0.4 per cent and actually decreased by 1 per cent immediately after the increase of oil prices in 1973–74. Energy research, nevertheless, has an important role in Italy and Germany, while in Denmark and the Netherlands most government expenditure continues to be "on the general promotion of knowledge".

The influence of defence research expenditure on the pattern of research in individual countries is catalogued in the CREST report. The disparity between the United Kingdom and its partners stands out. Thus British expenditure on defence research grew from 41 per cent of the government's budget in 1970 to 53.3 per cent in 1979. Only France comes anywhere near this proportion, with 35 per cent of the government's budget going to defence research in 1979. In the same year, Germany spent 11.7 per cent on defence research and the other six member countries little or nothing. The report does point out, however, that defence research brings industrial spin-off.

The outlines of the committee's picture remain clear enough. Research spending by Community governments is now increasing after the trough in 1978 but still falls short of American expenditure. (The Japanese statistics are incomplete.) In money terms, research and development expenditure in the United States in 1979 was about 1.3 times greater than the corresponding figure for the nine members of the Community. The good news, though, is that in 1980 (according to forecasts of US federal agencies) American government expenditure may have declined while that in Europe remained constant. **Jasper Becker**

Toxic chemicals

UK regulations

The long awaited and potentially contentious draft regulations by which the British government will require the notification of new chemicals were published by the Health and Safety Commission on Wednesday (18 February). The provisional timetable for discussion allows until July for comment, in which case the regulation could become law before the deadline of 18 September laid down by the European Commission. But Brussels, in this as in other matters, is running late and may not be in a position to make its 1979 directive binding on all member states until next year.

The draft regulations are substantially more stringent than the proposals described in the commission's discussion document published in 1977. The principle that they should apply only to new substances remains, but outline notification will now be required for substances manufactured or used in quantites of less than 1 tonne. Chemical manufacturers will now also be required to provide information about biodegradability, thus meeting one of the criticisms of the earlier proposals by environmentalists. One measure of the increased stringency of the draft regulations is that the estimated cost of testing a new chemical is now given as £45,000.

The proposed regulations for the United Kingdom are more stringent than those required by the European Community in that they apply to chemical intermediates as well as to products supplied to others. This is one of the points on which British chemical manufacturers are likely to concentrate in the coming months, but there will also be complaints that the proposed regulations allow the Health and Safety Executive to pass on to other European authorities information about

0028-0836/81/080622-02$01.00

chemicals newly introduced by British manufacturers.

Full notification (from which chemicals supplied to research laboratories will ordinarily be exempt) is elaborate. Manufacturers will be required by means of an acute toxicity test to classify new substances as toxic (LD_{50} less than 200 mg per kg), "very toxic" (LD_{50} less than 25 per kg) or neither, using oral doses in laboratory rats. Ordinarily, the chemical identity of the material will have to be defined, as will the purity of the material and "the nature and the concentration of the main impurities", which may be harder.

For most manufacturers, biological tests will be the most time-consuming. Apart from acute toxicity data (with oral doses in rats, subcutaneous doses in rats or rabbits and inhalation doses in rats), notification requires a 28-day sub-acute toxicity test, acute toxicity tests with fish and daphnia, tests for skin and eye irritation and of skin sensitization and a mutagenicity test. The regulations empower the Health and Safety Executive to require, on the basis of a preliminary examination of the first set of data (which has to be completed within 45 days) further information including the results of tests for teratogenicity and carcinogenicity.

Exceptions to the strict requirement of notification include the supply of chemicals required for further development and materials supplied in quantities amounting to less than 1 tonne (where chemical identity will usually be sufficient). One possibly attractive let-out is the provision that users of such small quantities may be able to meet the requirements by submitted a sample in a container labelled "CAUTION — substance not yet fully tested".

Industrial innovation

States chip in

Washington

Support by the states for technological innovation is becoming fashionable. Echoing a theme launched in Congress and by the federal government three years ago, several states are now beginning to put political force behind legislation intended to stimulate technological innovation in local industry. Many realize that their economic future may depend on their ability to attract and keep high technology companies in competition with rival bidders. Measures are therefore being introduced at the state level comparable with the federal initiatives proposed by President Carter two years ago for stimulating investment in high technology.

Often the new measures include the provision of substantial research funds for state universities to promote research in areas of particular commercial value such as the technology of microcomputers. Many states are also trying to draw their universities closer to the research and training needs of the private sector. Last week, for example, the state assembly of New York passed a package of four bills to promote the growth of high technology industry in the state and to forge closer links between the state government, private industry and local universities.

One of the New York bills would revivify the state's Science and Technology Foundation, originally established by Governor Nelson Rockefeller in 1973 to improve the quality of university research in the state. The new bill, likely to be accepted by the state senate and passed into law, would require the foundation, now virtually defunct, to help small companies obtain federal research grants such as those offered by the National Science Foundation. The bill also provides new incentives for colleges and universities to carry out potentially commercial research, and two members with management experience in high technology companies would be added to the foundation's board. A second bill, concerned specifically with research workers at the State University of New York, would increase the proportion of profits from the successful commercial development of research results that might be kept by a faculty member.

The growing interest of all states in the development of industrial policy has prompted a synposium organized this Saturday (21 February) in Washington by the governor of California, Edmund G. (Gerry) Brown immediately before the annual meeting of the National Governors' Association. Mr Brown has recently proposed a $22 million "reindustrialization" programme for California, claiming the need to forge a new partnership between government and industry. This demand was the basis of his unsuccessful bid for the Democratic presidential nomination last year — and is expected to emerge again in the 1984 election.

Central to Mr Brown's programme is a proposal to establish a Microelectronics Innovation and Computer Research Operation. This would be based at the Berkeley campus of the University of California and would focus on basic research in microcomputers considered too costly to be carried out by individual companies. The state would allocate $7.6 million to the project, $2.6 million to be spent by the university and the rest to be matched by grants from private companies, most of which have welcomed the proposal.

Similar plans are being worked up by other states. For example, the Minnesota state legislature is considering a request for substantially increased funds from the Microelectronics and Information Sciences Center at the state university. In North Carolina, whose governor, James D. Hunt, has promised to make the state the centre of the East Coast microelectronics industry, the government agreed last summer to allocate $1.8 million to a microelectronics centre in Research Triangle Park which has already tempted General Electric to commit $50 million to an integrated circuit plant nearby.

The Californian initiative is in part defensive. Because of high real estate prices and shortages of technical staff, many states are now sending delegations to Silicon Valley to persuade established semiconductor companies of the virtues of relocating elsewhere. Ohio has already been offering attractive inducements to companies prepared to move their operations, and while Mr Brown will be talking in Washington on Saturday, a delegation from New Orleans will be in California describing the advantages of the Deep South. **David Dickson**

Telecommunications

Monopoly intact

Halfway through the committee stage in the House of Commons, the British government has agreed to amend its telecommunications bill in ways that will please British Telecom but are unlikely to reassure telecommunications equipment manufacturers. The amendment will give British Telecom, the new telecommunications authority, the right to be consulted during licensing of equipment for attachment to the public telephone network. Manufacturers, already dismayed at the modest erosion of the public monopoly promised by the original version of the bill, now fear that their freedom to develop new communications technology will be further constrained.

The bill, introduced by Sir Keith Joseph, Secretary of State for Industry, last year, is the British government's watered-down equivalent of the steps taken by the US Federal Communications Commission to stimulate innovation by closer definition of the public monopoly in telephone systems. (Similar moves are under way in West Germany.) The British bill, which would split the mail-handling and telecommunications parts of the Post Office into two separate corporations, would leave British Telecom with total control of the telephone network but shade its monopoly on the supply of equipment.

The procedures in the original version of the bill for ensuring that attachments do not interfere with the operation of the network would take control from one bureaucracy, the Post Office, and give it to another, the Department of Industry. One of the amendments has it that standards will be set by the British Standards Institution in conjunction with British Telecom and the department; licences to manufacture equipment are now to be issued by the department after taking British Telecom's advice. Manufacturers complain that standards will take a long time to set and that British Telecom, potentially a manufacturer in its own right, will retain too much control. These issues are likely to be debated further before the

0028-0836/81/080623-02$01.00

committee stage ends, probably before the Easter recess.

Under the new arrangements, British Telecom will be able to manufacture and sell attachments only through independent subsidiary companies. Financing such ventures, however, will be difficult within the government's constraints on public borrowing. This is one reason why the government has amended the bill to allow British Telecom access to private finance. It may allow the corporation to work outside the public sector borrowing requirement, an issue not finally settled by the Treasury. One difficulty is that, whatever the source of capital, the government is still ultimately the guarantor.

In the next few months, equipment manufacturers will be keenly waiting to see how the removal of the monopoly is to be staged. The plan is to have a transitional period of three years during which the Department of Industry would control the market, giving British manufacturers time to plan for free competition. Much will depend on the Secretary of State for Industry, who is given wide enabling powers by the bill. Another open question is the arrangements for value added services. The bill gives the Secretary of State power to instruct British Telecom to allow private companies to lease part of the public network for the provision of services to third parties. What Sir Keith finally decides may depend on the outcome of a study by Professor Michael Beesley of the London Business School. **Judy Redfearn**

Carcinogen criteria

US retracts

Washington

Pressed by a recent Supreme Court ruling, US occupational safety officials have agreed to relax their previous opposition to including risk assessment calculations in decisions about reducing exposure to potential carcinogens. Hitherto, officials of the Department of Labor's Occupational Safety and Health Administration (OSHA) have argued that the scientific uncertainty of risk calculations — and the lack of an explicit requirement in the agency's authorizing legislation — meant that they should not be used as the basis of policy decisions. Instead, they have maintained that that once a substance has been demonstrated as a potential hazard, exposure should be lowered to the "lowest feasible level".

OSHA is being required to shift its position as a consequence of a decision by the Supreme Court last summer to strike down regulations which the agency had proposed for limiting industrial exposure to benzene (*Nature* **286**, 97; 1980). The court ruled that OSHA had failed to demonstrate that reducing benzene exposure limits from ten to one parts per million would reduce the level of "significant risk". Following this ruling, OSHA has now announced that it is revising its generic carcinogen policy, introduced last year as a mechanism for regulating any chemical suspected of causing cancer.

Under the terms of this policy, any chemical which meets one of a number of criteria — for example, which is shown to cause cancer in one experiment with laboratory animals, and also produces a positive result in a short-term test — is automatically labelled a carcinogen.

Originally, this would have been sufficient to invoke automatically the requirement that exposure be reduced to the lowest feasible level. Now OSHA officials have agreed to include consideration of whether the chemical poses a significant risk — using a variety of data to make this judgement, including court interpretations of previous rulings, OSHA's previous experience in regulating toxic substances and "prudent occupational health policy".

According to an announcement made in the *Federal Register*, three aspects of the benzene decision will be incorporated in the cancer policy. First, the significance of existing risk must be estimated before issuing a carcinogen standard; second, the exposure level must be set at the lowest feasible level which is "reasonably necessary or appropriate to eliminate significant risk"; and third, that OSHA must consider "all relevant evidence" in making such determinations.

This change in policy represents a significant shift from OSHA's previous position. The agency's former head, Professor Eula Bingham, has described risk assessment calculations as "abhorrent" to public health administrators; and the agency has strongly resisted pressure from government economists to push occupational regulations into a neatly quantifiable mould.

At the same time, the shift does not go as far as many in industry would like. Their demand is for full-scale cost-benefit analysis of all occupational health and safety regulations, based on the argument that federal controls have become a major economic burden. Although the Supreme Court, in striking down the benzene regulation, did not make the widely expected pronouncement on whether cost–benefit was required to demonstrate that a new regulation was "reasonably necessary", it is expected to do so in ruling on another case which has been brought against OSHA on cotton dust standards.

In any case, agency officials expect that a demand for full-scale cost-benefit analyses of future regulations — with the requirement that the least expensive option be adopted — will be one of the first ways in which the new Administration will try to meet its election promise of reducing the force of government regulations.

The labour movement, which has consistently argued that cost–benefit analysis is little more than a smokescreen designed to cover the relaxation of safety and health controls, is preparing for a fierce and lengthy battle. It has already complained about one of Mr Reagan's first anti-regulation acts, withdrawing new regulations published by OSHA in the last days of the Carter presidency which would have required the labelling of all hazardous chemicals used in the workplace.

David Dickson

Greenhouse effect

Act now, not later

Stockholm

The theme that the time has come for policy-makers to take account of carbon dioxide when drawing up energy policies ran through an Earthscan meeting on carbon dioxide, climate and, energy last week. But speakers' conviction that action should be taken now was matched by their caution in predicting exactly what would happen if carbon dioxide emissions continue to increase.

The fundamentals are broadly agreed. The pre-Industrial Revolution atmospheric concentration of carbon dioxide was about 290 parts per million, and the burning of fossil fuel has been the largest single factor contributing to concentrations which are expected to double by the middle of the next century, assuming a 2 per cent annual growth rate in the use of fossil fuels.

The reality of the greenhouse effect was also common ground between the speakers. Predictions about specific climatic changes in specific parts of the globe were, however, more equivocal.

Current models, according to Professor Bert Bolin of the University of Stockholm, are inadequate but "they are all we have". The models are especially inadequate in dealing with the role of clouds and the interaction of the atmosphere and the oceans. Dr Tom Wigley of the University of East Anglia pointed out the difficulties of distinguishing the signal from the noise: knowing when variations in regional climates stem from a particular factor such as carbon dioxide and when they are simply part of the continual natural variation.

Professor S.K. Sinha from the Indian Agricultural Research Institute in New Delhi was the only speaker daring to be at all optimistic, and even his belief that agriculture could adapt to climate changes was conditional on fruitful research being done on water management, the identification of new genotypes more tolerant of temperatures 3–4°C greater than at present and on higher crop yields with a smaller input of fossil fuels.

The most eloquent plea for energy policies to take account of carbon dioxide came from Gus Speth, chairman of President Carter's Council on Environmental Quality. In the last days of the Carter presidency, the council urged that "full consideration" should be given to carbon dioxide in the development of

0028-0836/81/080624-02$01.00

United States and global energy policy.

One of the first priorities in a preventive strategy would be to decide "what level of atmospheric carbon dioxide should be considered a prudent upper bound". Should we allow an atmospheric build-up of, say, 50 or 100 per cent over pre-industrial levels? The upper bound would carry with it implications for both developed and developing countries and would raise questions about the sharing of the fossil fuels whose use would be allowed.

Speth was not particularly optimistic about the chances of getting these things done. It is very hard to provoke an international response to an intangible problem whose consequences are not yet even predictable. Dr Thomas B. Johansson of the University of Lund could offer a little encouragement in that the sorts of energy policies desirable from a carbon dioxide point of view were also becoming increasingly necessary, in Sweden at least, for economic reasons. **Wendy Barnaby**

Plasma research

German setback

The Max-Planck-Institute for Plasma Physics at Garching has been forced to make a major reappraisal of its future. Because of government financial restraints (*Nature* 5 February), the institute's next major project, the "Zephyr" tokamak, has been cancelled. The institute, one of the three leading fusion laboratories in Europe, is now planning that its next project should be financed by a redistribution of resources within its total budget of about DM100 million a year.

Zephyr had been planned to leapfrog the joint European tokamak machine called JET, now being built at Culham in the United Kingdom, and would have experimented with ignited plasma. The hope now is that a redistribution of the budget will yield between DM20 million and DM100 million over the next seven years to build a less ambitious machine.

The reassessment at the institute will be carried out under new management. Last week, Professor Klaus Pinkau was appointed director of the laboratory. Although not a plasma physicist but a cosmic ray physicist, he has considerable experience of international collaboration, the politics of big science and the management of scientific institutions. He has been the director of the Max-Planck-Institute for Extraterrestrial Physics, next door at Garching, and is chairman of a committee reporting to the federal government on the merits of ten big science projects which, curiously, did not include Zephyr.

Pinkau said last week that it was dangerous to make scientific institutions too dependent on "annual changes" in the financial position of governments but, also, that budgets should not grow too fast. Certainly this year's changes at the Institute for Plasma Physics will give him pause: not only has Zephyr been deleted but the proposed budget for 1981 has been cut by 15 per cent. This trimming of sails may give the laboratory a sense of realism, persuading it that it cannot alone compete with JET, but a tough internal struggle seems inevitable between the advocates of an upgraded stellarator and a mirror machine. The edge might be taken off this battle if the new project were adopted by Euratom as a "preferred project", in which case between 10 and 20 per cent of the cost could come from Brussels. The advocates of an improved stellarator point to their success last year when the existing machine at Garching, Wendelstein VIIA, was used to show that a stellarator plasma could be held stable in conditions only previously obtained in tokamak machines. The same series of experiments created conditions of plasma density and confinement time more stringent than those reached by tokamaks of similar size, apparently putting stellarators back in business.

Tokamaks are in fact beginning to lose favour because of the various difficulties (fatigue and maintenance, for example) expected to arise in power reactors. Diversification is therefore considered prudent, whence current interest in stellarators and mirror machines. The Lawrence Livermore Laboratory in California is in fact building a mirror machine (the Mirror Fusion Test Facility) in which a large long solenoid is plugged at the ends with magnetic quadrupole mirrors. Garching cannot hope to compete with Livermore in money terms but, some argue, could attack the principles of such a device. This, broadly, is the second proposal being considered at Garching. A decision is expected in the middle of the year. **Robert Walgate**

Tokamaks and stellarators

In both tokamak and stellarator, plasma is confined to a torus by two superposed magnetic fields. One field runs around the torus, along its long circumference; the other winds round and round the small circumference of the plasma ring.

The first field is created in both tokamak and stellarator by a coil wrapped round the small circumference of the torus. The second is created differently in tokamak and stellarator.

In the tokamak, it is the result of a current carried in the plasma itself; in the stellarator it is the result of a component of current in the outer coils along the major circumference of the torus. As the plasma ring is electrically isolated, the tokamak must create the longitudinal current in the plasma by a transformer effect, and so must be pulsed.

The stellarator, on the other hand, can in principle be run statically. Early tokamaks — which were invented in the Soviet Union — were successful principally because of their large "aspect ratio" (major torus radius over minor), it is now believed, rather than because of any intrinsic merit of the tokamak design; and the need for pulsed operation is seen as a disadvantage in the construction of a true reactor, where the variation of thermal, neutron, and magnetic stresses could increase material fatigue.

Princeton perplexities

There are slippery hands and red faces at the Princeton Plasma Physics Laboratory, where a gaggle of lawyers is trying to decide who was responsible for dropping a 350-ton generator component during the construction of the Tokamak Fusion Test Reactor (TFTR).

The accident happened in December, when the outside stator of the vertical axis generator was being lowered into position. A crane bearing broke and the stator fell 15 feet, damaging both itself and the central rotor.

The incident is not expected to have a significant impact on the construction schedule for the TFTR, which will be used to achieve energy breakeven for the first time and to investigate the engineering features of large fusion systems. A second generator, already in place, will be able to supply sufficient energy for the test reactor, at least in the early phases of operation. However, a detailed study will now be necessary to determine whether the generator can be repaired — or whether a replacement is needed, which could cost up to $2 million, and take some time to deliver.

Present construction schedules anticipate that the TFTR will come into full operation in July or August 1982. This is about seven months later than the original completion date of December 1981, due largely to delivery delays on some of the major components — in particular the toroidal and ohmic field coils used to contain the plasma — which have presented more technical difficulties than expected.

Officials at Princeton say that they do not foresee any insuperable problems, as most of the technology is "state of the art". However, the delays will inevitably add to the construction costs, which are expected to exceed the predicted $284 million by about 10 per cent.

More than five subcontractors may be involved in the heated debate over the responsibility for December's accident. A report is expected shortly from the Department of Energy, which is expected to identify errors of judgement responsible for the crane overload. However, with large insurance sums at stake, any such conclusion is likely to be contested — and will almost inevitably end up in the courts.

0028-0836/81/080625-01$01.00

CORRESPONDENCE

Wrong rodents

SIR — The discovery that several cell lines claimed to be derived from patients with Hodgkin's disease in fact come from an owl monkey [1] emphasizes the vital importance of quality control in biological research.

Several cases of genetic contamination of inbred strains of laboratory mice and rats have come to light recently, and although these are not associated with any known scientific fraud, they have led in some cases to a considerable disruption of research projects. In the United States, for example, one large commercial breeder appears to have been selling "inbred" Lewis (LEW) rats which are not histocompatible, leading to a flood of complaints from research workers and inevitably casting doubt on the validity of some published work. In Japan, a survey of over 100 colonies of inbred mice [2] has shown that about 10 per cent had been genetically contaminated either recently (with continued genetic segregation at some loci) or in the more distant past. Indeed many of the major sublines of common inbred strains such as C3H and C57BL have arisen as a result of genetic contamination in the past [3].

In the United Kingdom a voluntary genetic monitoring scheme for commercial breeders was started about five years ago by the Medical Research Council Laboratory Animals Centre and several cases of genetic contamination have been discovered since that time [4]. Both of the main UK suppliers of inbred mice and rats took these results so seriously that they have established their own in-house genetic monitoring programmes run under the direction of consultant geneticists. The International Committee on Laboratory Animal Science (ICLAS) is preparing a handbook on methods of genetic monitoring, and is considering the establishment of some international reference centres for genetic monitoring. In the meantime research workers are strongly urged not to take the authenticity of the strains that they use entirely on trust. If they purchase animals from commercial breeders they should demand to know what steps the breeder is taking to monitor the stock. Those who breed their own strains should remember that accidental contamination can occur at any time, and they should check their stock using skin grafting or some other suitable method (such as the study of biochemical [5] or immunological markers [6] or morphological features such as mandible shape [7]) as a matter of routine.

French museums

SIR — Seen from this side of the Channel, Halstead's criticisms of the new exhibition policy of the British Museum (Natural History) appear extremely unjust (*Nature* **288**, 208; 1980), especially towards the staff who contributed to such clear and remarkable presentation. In France, there is no discussion of that sort, because most of our natural history museums simply have no exhibition policy at all, and are nothing but museums of museums!

Last November, when Halstead was writing his venomous letter, I visited the two new exhibits (on dinosaurs and on the evolution of man) at the British Museum, and was amazed to see how much the public liked them, in particular the children, who seemed very receptive to the logic of cladistic analysis. Halstead's long attack against that method of tracing the interrelationships of living beings deserves more comment. He claims that cladistic analysis, which is the basis of the British Museum exhibits, does not take into consideration the concept of gradualism, according to which evolution can be presented as uninterrupted series of species, older ones being ancestral to younger ones. Hence his accusation against cladism, which is, according to him, trying to make evolution fit Marxist views on the history of societies! Halstead presents gradualism as evidence, and cladism as a crime against evidence. But where is the evidence of gradualism? There is almost none, or rather it is everywhere one wants to see it.

Cladists do not deny that a species can give birth to daughter species, but they claim that in practice, it is impossible to determine the fossil ancestor of a species, since the ancestor is devoid of the derived characteristics of the daughter-species in question. Ancestor–descendant relationship is not, for cladists, a necessary statement, and the history of a group is better expressed by sister-group relationships, often illustrated by a cladogram. Many biostratigraphers are now convinced that successions of species based on stratigraphic distribution are nothing but illusions and that, in reality, each older species is extinguished by the younger one, whose centre of origin may be far from the locality studied. So, the subversive palaeontologists who are supposed to pervade the British Museum, knife between teeth, are simply those who consider that gradualism gives an illusory precision, which is unnecessary for tracing the course of evolution of a group. If these new views are congruent with vague ideological inferences on human societies, so what?. . . After all, the history of human societies often shows a succession of leaps, be they revolutions, wars, epidemics, or changes in climate. But major changes in human societies are seldom decided by the societies themselves. The societies and their chiefs want gradual change (compare the terms "changes in continuity" or "permanent revolution" used by right-wing and left-wing politicians respectively), but in the event, circumstances provoke sudden changes.

In France, some authors are now attacking Darwin (see P. P. Grassé, *L'homme en Accusation*, Albin Michel, Paris) because he is supposed to have inspired Hitler and still inspires the deeply anti-Marxist sociobiologists. Since cladism is also directly descended from Darwin's ideas on phylogeny and systematics, it can just as well be accused of supporting extreme right-wing ideologies.

In sum, even if some cladists claim that this method of analysis is more consistent with their political convictions, it is simply ridiculous to condemn it on the basis of such spurious arguments, or because Halstead's political opinions are different. The British educational system can be proud of the British Museum's exhibitions which will certainly teach future generations of biologists and palaeontologists the principles of phylogenetic reasoning. Perhaps this is just what Halstead is afraid of?

PHILIPPE JANVIER

Laboratoire de Paléontologie des Vertébrés,
Université Paris VI, France

More museums

SIR — Halstead's well publicized reactions[1-6] to the exhibition policies of the British Museum (Natural History), to non-gradualistic hypotheses about the evolutionary process, and to his own mistaken perceptions of cladistic analysis are unfortunate[7-9]. His notion that these views somehow abet non-scientific creationist metaphysics or logically support Marxist dialectics is preposterous. Whether Popper[10], Patterson[11], or Miles (cited by Halstead in ref.4) have said that the evolutionary concept is also metaphysically based and whether this is true are beside the point. Equating Marxist political theory either with cladistic analysis or with so-called macroevolutionary hypotheses is as wrong as social Darwinism was. It needs to be driven home, as Patterson has done[9], that cladistic analysis is about pattern, not about any particular hypothesized evolutionary process, although most phylogenetic systematists do hold that descent with modification is an economical explanation of the existence of biological pattern in general. These systematists also define "related" to mean "genealogically related." In all six publications Halstead confuses cladograms with evolutionary trees. For instance, a steady theme is, "there is no place for ancestral species in a cladogram"[2]. Again, "it is axiomatic, therefore, that no species in the fossil record can be ancestral to any other nor can one species evolve directly into another"[5]. Halstead has not understood that cladograms do not assume that species are ancestors, but neither do they deny possible ancestry when a taxon lacks known derived characters. Assumptions of ancestry are appropriate for trees but are not made in cladograms.

Cladistic analysis parsimoniously estimates relatedness and is therefore testable. The British Museum (Natural History) is to be congratulated for bringing epistemology into its exhibits and teaching visitors that science is a method, not a body of revealed knowledge. That the museum may also need to discuss various hypotheses of evolutionary process[12] and to address other needs as well, such as the public's thirst for discussion of functional anatomy, ecology, behaviour, and so on[13], is also evident.

Sir — I have read with diligence the continuing controversy sparked by Halstead. Thus far I have had difficulty achieving a precise understanding of it. Now, however, certain matters are clear (*Nature* 1/8 January, p.106.) To sum up: Halstead dislikes the new exhibits at the British Museum (Natural History), and he would convince other persons that they, too, should dislike the exhibits. The argument he gives, as far as my evaluation goes, passes not from the ridiculous to the sublime, but emanates entirely from the low end of that spectrum. Knowing Halstead to be usually of good cheer and judgement, I am led to suspect that not all is as it might seem — that the root of his dislike is not to be found brewing in a pot pourri of punctuated equilibria, Marxism, scholastic death, etc. Rather, his dislike may stem, as seems to me, from a sense of loss of "the fossil record" — the ultimate source of the truth of evolution as rendered by a professional class of fellow-specialists. To the dismay, sometimes acute, of the more clerically minded members of this profession, cladistics treats fossils in a secular fashion — not as revelation but as some among many other biological specimens subject to interpretation that is apt, indeed expected, to be diverse, especially with respect to details (for example, the true nature of the "Petralona skull"). As reasonable as this treatment might seem to the outsider, the emotional effect within such a palaeontologist involuntarily confronted with cladistics (as I have witnessed on more occasions than I care to remember) is not unlike that apt to be experienced by a fundamentalist minister who has forced upon him uninvited the notion that the Bible is just one book among many. Suffice it to say that more than one kind of church has been built upon rock.

So what now? Here in the States creationists dislike the museums' secular exhibits on evolution and the schools' secular treatment of that subject. In Britain a palaeontologist dislikes secular exhibits on the "fossil record". The forms are similar, but the substances at first glance seem utterly different. Palaeontology, after all, is nominally a science, and a rational mind can easily defend it as such. The problem I have with Halstead's defence, if I may term it that, is reconciling it with a standard of rationality.

Genes and racism

Sir — Steven Rose notes in his recent letter (*Nature* 22 January, p.335) that a National Front journal *New Nation* has claimed to find support for racism in my writings on sociobiology, as well as in those of Dawkins and Maynard Smith. Rose calls on the latter two authors to dissociate themselves from such misuse, although curiously he does not extend the same invitation to me. To keep the record straight, I am happy to point out that no justification for racism is to be found in the truly scientific study of the biological basis of social behaviour. As I stated in *On Human Nature,* "I will go further and suggest that hope and pride and not despair are the ultimate legacy of genetic diversity, because we are a single species, not two or more, one great breeding system through which genes flow and mix in each generation. Because of that flux, mankind viewed over many generations shares a single human nature within which relatively minor hereditary influences recycle through ever changing patterns, between the sexes and across families and entire populations".

If there is a possible hereditary tendency to acquire xenophobia and nationalist feelings, it is a *non sequitur* to interpret such a hypothesis as an argument in favour of racist ideology. It is more reasonable to assume that a knowledge of such a hereditary basis can lead to the circumvention of destructive behaviour such as racism, just as a knowledge of the hereditary basis of haemoglobin chemistry and insulin production can lead to the amelioration of their pathological variants.

I now call on Professor Rose to consider these and similar arguments raised in my writings. It is my hope that he will not confine himself, as he has in the past, to arguments that link sociobiology to racism and thus to continue to abet the very misuse which he piously claims to deplore.

Origin of cancer

Sir —John Cairns' article on "The origin of human cancer" (*Nature*, 29 January 1981, pages 353-357) dismisses the importance of chemical mutagens in human cancer aetiology on, we believe, very tenuous grounds. He argues that there must be a single underlying mechanism for tumour production and that this is not through point mutation. As your leading article (*Nature*, 5 February 1981) quite rightly points out, why should there be a single mechanism for cancer development? Indeed, can one say that cancer is even a single disease? Cairns' article appears to us to be a simplistic approach to a complex problem. We all would like to have the answer to how a cancer cell develops, but can one say that Cairns' article will lead us any nearer to the truth? Why should workers in the field of chemical carcinogenesis abandon a large body of work which may be getting somewhere near to establishing why populations differ in cancer incidence, and substitute a hypothesis of genetic transposition bearing in mind that, as Cairns writes, it is not yet clear whether transposition is important in vertebrate development. Should we abandon the somatic mutation theory of cancer for a hypothesis with no experimental evidence? Furthermore, why should mutagens/carcinogens only act through point mutations? It is well recognized, as Cairns states, that agents reacting with mammalian cell DNA can cause gross effects such as chromosome aberrations, sister chromatid exchanges, deletions, and so on. Just because one measures DNA reaction in bacteria with a point mutation system does not mean *a priori* that this is the mechanism of action of these chemicals in mammalian cells. After all, bacteria don't even get cancer. Bacteria are merely used for carcinogen screening because they are cheap and mutations are easy to score.

Where Cairns' article is mischievous is in suggesting that people are wasting their time looking for carcinogens in the environment and then, having identified them, seeking to reduce exposure. The fact is that if people would stop exposing themselves and their immediate families to mutagens/carcinogens in the form of cigarette smoke, a large proportion of cancers would be prevented (besides a large proportion of coronary heart disease, lung disorders, etc.). If Cairns accepts that smoking is bad for one, why should he not accept that other environmental insults might also be carcinogenic? To say that animal carcinogens induce mainly liver cancer, that humans don't normally get cancer of this organ, and therefore animal liver carcinogens have nothing to do with human cancer shows a complete unawareness of chemical carcinogenesis. Most chemicals which have been identified as human carcinogens do *not* give the same spectrum of tumours in animals as in humans, for example benzidine causes bladder cancer in man but liver cancer in animals.

Cairns' main argument for DNA reaction being unimportant in carcinogenesis is the finding that in xeroderma pigmentosum patients, few if any internal cancers have been seen. Why should one expect an increased incidence of lung cancer, for example, in these patients? Is the skin the same as the lung in its function, biochemistry, enzyme profile, etc.? Why should we expect the mechanism of skin cancer to be the same as for internal organs? Do xeroderma pigmentosum patients live in the same environment as the normal population? I don't think one has to indulge in "special pleading" to support the case of somatic mutation as being important in cancer production. The majority of facts available tend to support the somatic mutation hypothesis. When there are sufficient data available to overthrow this hypothesis, then is the time for it to be abandoned. In the meantime, those of us working in chemical carcinogenesis will carry on identifying carcinogens in the environment and recommending that exposure be reduced. Whether society (or Cairns) listens to us is entirely up to them.

The Great Badger Debate

What follows is a brief summary of the report Badgers, Cattle and Tuberculosis, *published by the British Ministry of Agriculture, Fisheries and Food last October and a comment by its author, Lord Zuckerman, on various criticisms that have been raised, some of them in* Nature

Report and implications

Bovine tuberculosis has been recognized as a serious problem in the United Kingdom (and also a source of human tuberculous infection) at least since 1913, when steps were first taken to control the disease. Farmers were encouraged to register herds free from tuberculosis by means of a premium price for the milk they produced, and infected cattle were also slaughtered compulsorily. But bovine infection continued, with unexplained "breakdowns" even in attested herds.

The link between bovine tuberculosis and badgers was first recognized in 1971, with the discovery of tuberculous lesions in a badger found dead. The organism responsible was found to be *Mycobacterium bovis*, that responsible for bovine tuberculosis. It now appears to be common ground that badgers can be infected by this organism. In 1975, ministry officials began controlling badgers found within a specified radius of infected herds of cattle by the use of cyanide gas. These procedures were abandoned in October 1979, but have been resumed in South West England since the publication of the Zuckerman report.

The transmission of tuberculosis from badgers to cattle is accepted in the report, which says that viable *M. bovis* have been recovered from grass sprayed with the urine of infected badgers (but more easily in the winter than the summer). The report also says that during the period in which control by gassing was carried out, "185 out of 2,432 badgers that had been collected in the vicinity of 477 farms where breakdowns had occurred" turned out to be infected with *M. bovis*. The report also records how, in New Zealand, the opossum was discovered to be a reservoir of bovine tuberculosis, and gives (in its Appendix III) accounts of how, at several farms in South West England, infection in badgers has been linked with breakdown among herds of cattle.

The South West of England sustains a third of the United Kingdom's cattle, and also dense populations of badgers. It is common ground between Lord Zuckerman and those who have criticized his report that badgers are also prevalent in parts of England, where bovine tuberculosis is rare. Lord Zuckerman concludes, in his report, that the population density of badgers determines both their susceptibility to infection and the risk of transmission to cattle. The frequency of infection among badgers in the South West of England has been found to be as great as one in five in some places.

Among the recommendations in the report were the resumption of badger control by gassing in the South West, the investigation of the incidence of tuberculosis among badgers in contiguous parts of the country, financial support for field studies of the British badger population, the publication of annual reports of the progress of the control campaign and a more thorough review of what will by then have been learned of the badger problem after an interval of three years.

Zuckerman's case

The 6 November 1980 issue of *Nature* (p.6) carried a brief account of a report on tuberculosis (TB) in badgers and cattle which I had prepared for the Minister of Agriculture, Fisheries and Food. The report was written in response to a request for an assessment of the soundness or otherwise of the scientific evidence on which the ministry based the view that badgers in parts of the South West of England constitute a reservoir of the bovine tubercle bacillus. Because of its statutory responsibility to suppress TB in cattle, I was also asked whether the government was justified in its policy of destroying badgers where there was presumptive evidence of the presence of tuberculous badgers that might be responsible for outbreaks of TB in neighbouring cattle.

During my investigation I had consulted several scientists engaged in the study of animal disease, as well as practising veterinary surgeons. All agreed with the findings of the ministry's scientific and veterinary officers with many of whom I had conferred. My own review of the evidence left me satisfied that badgers in certain areas of the South West are heavily infected with the bovine tubercle bacillus, and sometimes transmit the disease to cattle grazing on pasture that has been contaminated with their sputum, pus, urine and faeces. I uncovered not a vestige of scientific foundation for widely publicized statements from "protestors" to the effect that none of the story was "true" and that, in effect, the whole thing was a hoax perpetrated by government servants.

It was, of course, unlikely that a fresh display of the facts would necessarily succeed in "converting" the opposition. But it came as a surprise to read first, in an unsigned article in *New Scientist* (4 December 1980, p.619), and then in a letter published in *Nature* intended as a corporate statement by The Mammal Society (11 December 1980, p.532), that the conclusions of my report, in which I had assembled not only more, but also more up-to-date, information on the subject than had been made available before, were questionable on scientific grounds. Apart from agreeing that "the badger is a major reservoir of bovine TB in certain limited areas of South West England, and hence a potential danger to the cattle in those areas", the society asserts that my report gave a "biased interpretation of the evidence", that "many of (my) conclusions were not justified" by the data which I had presented, and that "factually misleading statements" therefore needed to be corrected.

The report

My main conclusions, set out in the report, were first, that "by any rational epidemiological standards, badgers (in some parts of South West England) now constitute a significant reservoir of the bovine strain of the tubercle bacillus". The Mammal Society thinks otherwise. It declares that "there is no scientific evidence to justify" the view that badgers in the affected areas constitute "a highly infected population". If the society is sufficiently well informed to make this extraordinary claim, the onus of providing proof, as Dr Plowright has already pointed out (*Nature* 1/8 January 1981, p.8), is on them.

Next, the Mammal Society was, to say the least, irresponsible in their quotation of what was in the report. I did not "overlook" the fact that during the first seven months of the moratorium the percentage of badgers with TB had fallen slightly in Cornwall at the same time as it had increased in Gloucestershire and Avon; this is precisely what my figures revealed. Nor did I interpret these or any of the other available figures in the "black or white" way that the Mammal Society suggests I did and, now in reverse, that it itself does. The interpretations I provided were the best that could be put on the figures, and were carefully qualified. Conclusions contrary to those I drew from the facts would have been absurd.

The Mammal Society is not criticizing when it merely repeats what I emphasized: namely, that the disease in badgers occurs only in "pockets". But it is falsifying what I did write when it says that I had asserted that badgers in the affected areas of the South West are spreading TB to badgers in other areas. What I wrote was that no one knows how one pocket of infection in badgers relates to another (paragraph 134 of the report). And I did not say that TB *is* (my italics) a major hazard to the survival

0028-0836/81/080628-03$01.00

of the badger (even if it clearly is to the badgers in the areas already affected). What I said was, were the disease "to take hold in badgers in other parts of the country" "there is no saying what the consequences would be . . . as they relate to the survival of the badger".

In considering the persistence or extinction of a disease in a given locality, the statistical laws governing its spread must be borne in mind. If the average number, x, of new infections from a unit which becomes infected is less than 1, the disease will die out. If greater than 1, the disease, once established, will spread. However, if x is not markedly greater than 1, there is still a good chance that a single infection will not result in its establishment; but if repeated new infections occur, then eventually one of them will be successful in establishing the disease.

With badgers two separate units are involved: first, the individual within a badger sett, and second, the setts themselves. As Dr Plowright has re-emphasized, the epidemiological conditions are highly favourable for transmission of TB within a sett. Transmission between setts seems to depend very greatly on such factors as density of population, contiguity of setts, and fighting between members of different setts. In an area which adjoins another where the disease is endemic, there will be a continuous flow of infection from the infected area to the border setts of the other area. But if x for the second area is less than 1, the infection will not spread through the whole area.

Infectivity

It is obvious that the period during which a unit remains infective depends on the nature of the disease. For a disease which kills quickly or in which there is complete recovery without the unit becoming a carrier, the period will be short. In a disease such as TB it will be considerably longer. Note also that the value of x will change with time, both because of the direct effect of the disease on population density and of acquired immunity, and also because of other unrelated factors.

I have discussed these matters with Dr Frank Yates of Rothamsted. In his view, my supposition that bovine TB may have been prevalent in badgers throughout the country before its virtual eradication from cattle is almost certainly justified (paragraph 133 of my report). After its eradication from cattle and the consequent absence of cross-infection the disease died out in areas of the country in which x was less than 1, as it seems to have done in most of the UK.

Dr Yates has also pointed out that once the disease has died out in an area, this area will remain free as long as no new infection is introduced, but if owing to an increase in the density of population or for other reasons x becomes greater than 1, the disease, once established, will then spread until the whole area is infected. The question put by the Mammal Society as to why areas in other parts of the United Kingdom with a badger population density which is presumed to be as great as in the South West were not infected, seems basically simple. Either x has remained less than 1, or they have just been lucky.

Before turning to certain further information about the prevalence of TB in badgers that has become available since my report was written, it is necessary to refer to what I said about the incidence of breakdowns in cattle, since this is also something about which the Mammal Society is critical.

The campaign to suppress bovine TB resulted in a decline in the incidence of reactors in cattle herds, not only in the South West, but also in the rest of England. This the Mammal Society acknowledges. But, as Dr Plowright has already pointed out the society failed to note in its statement the critical fact that while the incidence of herd breakdowns has fallen dramatically in all parts of the country once the culling of tuberculous cattle was made compulsory in 1950, in the affected areas of the South West it has consistently remained more than five times the national average. This difference was the essential reason for the search for a "cause", and for the resultant finding of a reservoir of the bovine tubercle bacillus in badgers in the affected areas. And here is where the Mammal Society's criticisms have gone wildly astray. Their suggestion that one possible interpretation of the figures given in the Report was that unknown "subtle factors" resulted in a decline of TB in both cattle and badgers throughout the country, and that gassing had little significant effect on the overall timing or rate of decline is, as Dr Yates has shown (*Nature* 22 January 1981, p.218), based on a very superficial and distorted use of the evidence. His more detached presentation clearly indicates that the gassing campaign appears to have had a considerable effect in reducing the very high incidence of herd breakdowns in the worst affected parts of the South West. What the Mammal Society did was lump together in a graph my figures for TB in badgers in all the affected counties of the South West, whereas as Dr Yates has shown, there is a radical difference when one compares the parallelism in the prevalence of TB in badgers and the incidence of breakdown in cattle as between Cornwall and Gloucestershire on the one hand, and Devon, Dorset, Somerset and the rest of England on the other.

In its haste to criticize, the Mammal Society has also clearly failed to realize that the data assembled in my report were the best available at the time, and that more would be published as they became available — I have recommended annual reviews. The society's charge that it was "manifestly untrue" that herd breakdowns reflected a high local prevalance of TB in badgers was based on the figures for Cornwall, where only 15 per cent (51/340) of the breakdowns were attributed to badgers. What the society failed to bring to the attention of its readers — their examination of the evidence must indeed have been cursory if they themselves failed to notice it — is that, as Dr Yates did note, in Cornwall 69 per cent (234/340) of the breakdowns were classed as unknown, whereas in the rest of the South West (plus Sussex) only 26 per cent (107/417) were so classed, 67 per cent (280/417) being attributed to badgers.

Lord Zuckerman (right) with Agriculture Minister Peter Walker and the report

Figures

Before rushing into print the society might indeed have enquired further about the Cornish figures. I have now obtained a breakdown by years which gives:

Cornwall	*Unknown*	*Badgers*
1972–73	110	–
1974–75	88	10
1976–78	36	41
	234	51

The explanation is simple. Badger investigations were only begun in Cornwall as a routine measure in 1974. The progressive reduction in the proportion of "unknowns" indicates their increasing thoroughness. I am also informed that for the whole of Cornwall 72 per cent of the 51 outbreaks attributed to badgers were within 2 miles of setts containing infected badgers, and 33 per cent were within half a mile. For the West Penwith area the corresponding percentages were 97 and 47.

The data which I had when I wrote my report related to only the first seven months of the period of the moratorium (Table 18 of my report). I have now been provided with figures for the first twelve months during which no new gassing operations were carried out. During the year, 611 badgers were autopsied in connection with official investigations to determine the source of herd breakdowns in the affected areas of the South West, and 73 (12 per cent)were found to be infected. Needless to say, there were differences between the counties concerned, but since the significance of these differences could only be determined through a detailed analysis aimed at revealing their relation to specific herd breakdowns, they hardly merit discussion.

More important is the information that is now available about the herd breakdowns that occurred in the affected areas in the first twelve months of the ban, about which nothing positive could be said on the basis of the data that were made available to me when I drew up my report, and in which reactors were found in only 0.7 per cent of the 17,411 herds that were tested. Between April and September a further 6,845 herds have been examined, bringing the total up to 24,256. The percentage of reactor herds had risen substantially in comparison with the first seven months of the moratorium in every one of the affected counties of the South West. Overall, the percentage for the period April to September was 2.2, double that for the period January to September 1979. For the year of the moratorium as a whole it was some ten times higher than for the rest of England.

The anonymous article in *New Scientist* (4 December 1980) referred not only to the Mammal Society's statement, but also (1) to certain critical comments by Dr Hans Kruuk that follow the same line as the society's statement; and (2) to an assertion by Miss Eunice Overend, described as an "enthusiast" of badgers, about the speed with which TB develops in badgers; she is quoted as saying that while TB may develop quickly in captive badgers, "it wouldn't happen in the wild". In answer to an enquiry I put to her, she also challenges the views of veterinarians about the speed with which the disease can take hold in cattle.

I have no doubts about Miss Overend's sincerity, but her "facts" happen to be wrong. Advanced TB lesions have been found in the lungs of wild badger cubs ranging in age from four to nine months, which had clearly been infected by routes other than bite wounds, and it is estimated that at least some of these cubs would have succumbed to the disease in a matter of weeks.

Anomalies

Of course, there are still many "anomalies" in the story, which further enquiry might elucidate. But every one of the so-called anomalies referred to in the Mammal Society's manifesto, all its speculative questions, "why this, why not that", are, as Dr Plowright has pointed out, mentioned in my report. Setting them out as a form of criticism adds nothing to the story. I hope that the further enquiries which I suggested should be undertaken to clear up a number of "unknowns", and which the Minister of Agriculture, Fisheries and Food, in his statement to Parliament said would be started as soon as the necessary arrangements can be made, will be entrusted to experienced and competent hands.

So much for the "scientific" criticisms that have been levelled at my report. No new facts have been brought forward. Nothing that has been said would make it anything but irresponsible for the government to devise a policy of action for the suppression of bovine TB, to which it is statutorily committed, other than what it is doing. Unfortunately, the Mammal Society's statement has been used as part authority for a press-release by the UK branch of the World Wildlife Fund, in which the government's acceptance of my report is in effect condemed. This was issued without any consultation with the Animal Health division of the Ministry of Agriculture, Fisheries and Food (MAFF).

As a scientist I have been a dedicated supporter of the conservation movement since before the Second World War,and as a scientific adviser to government I played a part in organizing our own formal institutions for the protection of the environment. I therefore find it regrettable that the only way I could have found favour with those who are concerned to obstruct the government's anti-bovine TB policy would have been either to suppress, or to fudge, the evidence which had been gathered by those scientists primarily concerned over many years with the problem of TB, not only in cattle, but also in badgers (as well as in those luckier representatives of the wild fauna of the country which, by comparison, are relatively resistant to the infection).

Mammal Society

The Mammal Society was one of the bodies which submitted written evidence to help my enquiry, citing Stephen Harris and Dr Kruuk as its two authorities since, so the Society said, they were "the two principal non-MAFF scientific researchers on badgers in this country". Presumably both helped in the drafting of the corporate statement which was designed to correct my "factually misleading statements". Since there can be few land-mammals that have generated as much proprietary interest as has the badger among the handful of naturalists who have added to our knowledge of the ways of the animal, I should note that I cannot find in the zoological literature any paper by Harris on badgers. Dr Kruuk's present studies relate to the animal's natural history, and I referred (paragraph 141 of my report) to a proposal which he had already published, that "pastures in infected areas should be so dressed as to reduce drastically the population of earthworms which they sustain", commenting, however, that I did not know "whether there is a way of doing this without detriment to the cattle which also forage the pastures that would be treated", nor "what those concerned with the welfare of birds — which also eat worms — would think about the measure which Dr Kruuk has proposed" Before turning to the badger, Dr Kruuk studied the behaviour and ecology of gulls and carnivores — mainly hyenas. For this work he was awarded the Zoological Society's Scientific Medal in 1975.

The errors in the Mammal Society's statement suggest that its badger panel did not include experienced epidemiologists or veterinary scientists. That it should have done is clear. For contrary to what has been said to me by the society's president, Dr Ernest Neal, the study of mammals is not just "a rather narrow field of interest" that can be covered by watching the behaviour of animals in the wild. Whether or not it was intended, the misleading impression which the statement has made on the media, and on those who now clamour against the government's decision, was that the Mammal Society is a body that can make pronouncements on animal disease which, if anything, might have been expected from the Royal College of Veterinary Surgeons, or from a commitee set up *ad hoc* by the Royal Society.

Of course members of the Mammal Society are free if they so wish to criticize the scientific validity of the data that I collected and to question my interpretations, but by insisting that it has the right to make a corporate, but anonymous, statement of the kind it has the young Mammal Society has, in my view, done itself harm. Here it is useful to refer to the main editorial in *Nature* of 11 December 1980 (p.525) entitled "Code of conduct for national academies", which pointed out that even "The Royal Society has no means by which it can reach a corporate opinion on any substantial issue of public policy . . . for example, say, government policy on nuclear power stations or whether manufacturers of drugs should in future be liable for side effects". Of course, the Royal Society could set up committees to look into such matters, but then its members would be named, and those Fellows of the Society not on the committees would certainly not be committed to whatever recommendations were put forward. If it wishes its published statement to be considered further then the Mammal Society should clearly name the "experts" who were responsible for its drafting. Dr Yates suggests that what the Mammal Society has done illustrates "the way in which distorted and partial graphic presentation can be used for propaganda purposes". It might have been more charitable to say that what was done was done out of ignorance. But then, as Gunnar Myrdal has put it, one has to remember that ignorance, like knowledge, can be steered for a purpose.

Not only was there no scientific value in the Mammal Society's statement; it was clearly the work of only a handful of its members, none of whom, so far as anyone can tell, had ever worked on the epidemiology of tuberculosis in animals. It is unfortunate that the society's action should have encouraged those who protest against MAFF's findings and policies in the belief that they have scientific support for the new wave of opposition which they have already mounted.

NEWS AND VIEWS

Too soon for the rehabilitation of Lamarck

CAN acquired characteristics be inherited? The arresting letter from Gorczynski and Steele (on page 678 of this issue) says that there are circumstances in which they can be. The interest of the observations is beyond dispute. The days have long since gone when dark lamarckian issues such as these could be raised respectably. Even in primary schools, or at least in those not yet captured by the creationists, young people are now told that the giraffe did not come by its long neck because earlier generations of giraffes had stretched their necks in an attempt to eat the leaves of ever-taller trees, and had been able to pass on the characteristics thus acquired. So how can it be that dark lamarckian evidence can be uncovered at this late stage in the study of inheritance? That is what many people will be asking. The simple answer is that it is too soon to know what to make of the observations now reported. On such an important issue, no single set of observations can be sufficient to overturn the accepted view of how inheritance is organized in living things. Independent confirmation is now the most urgent need. So much has been clear since the first article on this subject by Gorczynski and Steele a year ago (see R.B. Taylor *Nature* **286**, 837; 1980). By all accounts, confirmatory evidence has been hard to come by. Some reports of failures to confirm seem destined to appear in the next few months. Gorczynski and Steele, like their would-be critics, have chosen an intricate field in which to work. For the time being, however, the results they report must be put firmly in limbo. They do not constitute a proof that Lamarck has been right all this past century and a half, but only a question to be pondered.

The lamarckian heterodoxy, it must be remembered, had respectable beginnings. Lamarck had the wit to recognize the need for an explanation both of the diversity of species and the evidence for evolutionary processes uncovered (by the Lyells of this world) from the sedimentary rocks. At the outset, the notion that characteristics once acquired might be inherited cannot have failed to be seductive. What could have seemed more sensible, in the first half of the nineteenth century, than that a giraffe with the good sense to stretch its neck in the search for better food might produce offspring with similar characteristics? The difficulty, from the beginning of the Lamarckian thesis, is that it has never amounted to an explanation. If the giraffe came by its long neck thanks to the diligence of its ancestors, why does not a woman whose arm is amputated produce one-armed children? Lamarckians, both ancient and modern, have not been able to answer such questions.

Historically, none of this has mattered very much. Darwin's explanation of both diversity and the appearance of change, or evolution, turned out to be a better explanation. Both diversity and change, said Darwin, could be explained by the mechanism of evolution by natural selection. Longer-necked giraffes might be fitter in the sense of being the more able to propagate themselves. So much is now accepted, yet darwinian scholars are forever gleefully discovering in *The Origin of Species* or other darwinian texts evidence of Lamarckism in Darwin himself. So what? Formally, Lamarckism and Darwinism are not mutually exclusive. One does not disprove the other. Although Darwin showed that natural selection is the predominant process in evolution, the data available in the second half of the nineteenth century could not have excluded the admixture of a modicum of lamarckian inheritance. The contemporary orthodoxy stems not from Darwin but from the turn of the century. The rediscovery of mendelism provided a mechanism by which variations could arise and thus be selected. Weissman's doctorine that there is a sharp distinction between the cells of the germ line and the soma meanwhile outlawed Lamarck. In modern language, according to Weissman, the genotype has a decisive influence on the phenotype, but the phenotype can affect the genotype only because the phenotypically fitter individuals are more adept at the propagation of their own kind. So far, everything that has been learned about the mechanisms of ineritance in animals and plants is consistent with both Darwin and Weissman.

Laboratory experiments in which viruses have been shown to carry new information into the germ line are nevertheless a tantalizing hint that there may be exceptions to the rule. Gorczynski and Steele challenge Weissman's doctrine, not the belief that darwinian selection is predominant in the evolution of species. Their latest experiments are an extension of those described a year ago. Then, they claimed that male mice made tolerant to a single histocompatibility antigen produced, from normal mice of the same strain, offspring that were also tolerant of the same antigen, at least in the first and second generations. The acquired characteristic (tolerance of a specific antigen) appears to be inherited. The latest series of experiments begins with male mice made tolerant of two antigens. Again, the data seem to suggest, tolerance to both antigens appears in the first and second generations. On the evidence available — and the numbers are only small — the two acquired characteristics are transmitted independently to the first and second generations of mice. Gorczynski and Steele put forward a possible explanation of their results. Weissman's doctrine has been violated, they say, because some naturally occurring RNA virus may have picked up the altered genes from the immunological system of the mice made tolerant to histocompatibility genes, and may have transferred these to the germ line. The results, they say, "demand an explanation not offered by conventional neo-darwinian genetics".

Not everybody will agree. For one thing, the experiments so far described are incomplete. If, indeed, a somatic mutation has been transferred from the soma to the germ line, then it should be possible to select both male and female mice of the first generation carrying the gene for tolerance and demonstrate that, thereafter, the mice breed true. In reality, the frequency of tolerant individuals is less in the second generation than the first, suggesting that whatever is being inherited cannot be fixed in the germ line. Moreover, there are other possible explanations for the results so far reported. One suggested by R.B. Taylor is that the mice may have inherited not the gene for tolerance but a gene for the production of the antigen used for the induction of tolerance. Other explanations will emerge. While so little is known of the mechanism of tolerance in these mice, and while conventional explanations have not been ruled out, it is premature to call for a recasting of genetics, "neo-darwinian" or otherwise. And the experiments need to be repeated.

Gorczynski and Steele will no doubt

0028-0836/81/080631-02$01.00

regard this response to their interesting article as toffee-nosed. Others, sadly, will go further and say that even a single case of the inheritance of an acquired characteristic implies that contemporary genetics is a house of cards. That is an outrageous leap ahead.

Even if the data now reported are confirmed, the explanation of them offered by Gorczynski and Steele may turn out to be no more than an exception that proves the conventional rule. For if it requires the extreme procedures that have been used in these experiments to provoke such an indecisive example of lamarckian inheritance, may not the generality of Weissman's doctrine be strengthened? Even that speculation is however premature. It will be time enough to worry about the rehabilitation of Lamarck when and if the data now reported are independently confirmed. □

Gamma-ray astronomy

from R. D. Wills

THE spectral range of gamma-ray astronomy is very broad. At a recent meeting* results were presented and discussed which span seven decades of photon energy from about 10^5 to more than 10^{11} eV. The techniques described differ considerably along the energy range, but essentially two approaches are adopted to overcome the problem of atmospheric absorption. At the lower energies, where the fluxes are relatively higher, instrumentation is carried above the atmosphere by balloons or satellites. Above about 10 GeV it is advantageous to measure at sea level or mountain altitude the secondary particles generated by interactions of the primary radiation in the upper atmosphere. These secondaries can be detected over a wide area enabling very low fluxes to be measured.

Most of our knowledge about high-energy (30 MeV to 5 GeV) gamma rays has been obtained from the NASA satellite SAS-2 (C. E. Fichtel *et al. Astrophys. J.* **198,** 163; 1975) and its ESA successor COS-B (L. Scarsi *et al. Proc. 12th ESLAB Symp.* ESA *SP-124,* 3; 1977). The latter has made the first complete detailed survey of the Milky Way in high-energy gamma rays (H. A. Mayer-Hasselwander *et al. Ann. N. Y. Acad. Sci.* **336,** 211; 1980). On behalf of the Caravane Collaboration, H. A. Mayer-Hasselwander (Max-Planck-Institut für Extraterrestrische Physik, Garching bei München) reported that, up to the end of 1978, 83,233 gamma rays had been recorded from the galactic disk (latitudes $|b| < 12°$) and outlined the current analysis of their spatial distribution and energy spectrum. A. W. Strong and A. W. Wolfendale (University of Durham) reviewed the results at intermediate latitudes ($10° < |b| < 20°$). As in the lower-latitude range, the gamma-ray intensity is well correlated with the various tracers of the constituents of interstellar matter. The use of galaxy counts as a tracer of the 'total gas' enabled the gamma-ray emissivity of the interstellar medium to be obtained. Its energy dependence showed clearly the importance of the contribution of cosmic-ray electrons to the generation of gamma rays. G. F. Bignami (Istituto di Fisica Cosmica del CNR, Milan) drew attention to low-latitude correlations with galactic structures on a variety of scales, and pointed out that inconsistencies between the gamma-ray map and Gould's Belt could be explained in terms of the newly discovered 'Dolidze Belt' (M. V. Dolidze *Sov. astr. Lett.* **6,** 51; 1980).

Several speakers discussed the localized gamma-ray sources, of which 25 are listed in the 'Second COS-B Catalog' (B. N. Swanenburg *et al. Astrophys. J.* in the press). P. A. Caraveo (Istituto di Fisica Cosmica del CNR) described a search for X-ray counterparts in the error boxes of some of the unidentified sources, whose positions are known only within a radius of about 1 degree. On the basis of their narrow latitude distribution R. Buccheri (University of Palermo) proposed that at least a significant part of them could (like the only two unambiguously identified sources, PSR 0531 + 21 and PSR 0833–45) be very young pulsars, but ones not yet known to radioastronomers. A complementary suggestion by T. Montmerle (Centre d'Etudes Nucléaires de Saclay) was that a class of gamma-ray sources is extended sources, associated with selected active regions in the Galaxy, like the ϱ Oph cloud or the Carina complex.

Extragalactic gamma rays were reviewed by D. Ramsden and A. J. Dean (University of Southampton). In the high-energy range only the quasar 3C273 has been detected (G. F. Bignmai *et al. Astr. Astrophys.* in the press), though upper limits exist for the fluxes from many active galaxies and some galaxies in the local group (G. F. Bignami *et al. Astrophys. J.* **232,** 649; 1979; A. M. T. Pollock *et al. Astr. Astrophys.* in the press). The Seyfert galaxy NGC 4151 has been detected below 20 MeV in balloon experiments (F. Perotti *et al. Nature* **282,** 484; 1979) but lack of confirmation from other experiments indicates that it may be variable at these energies, as it is in other parts of the electromagnetic spectrum. In this energy range it is possible to detect gamma-ray line emission due to nuclear interactions or antiparticle annihilation (R. Ramaty and R. E. Lingenfelter *Nature* **278,** 127; 1979). The experimental status of such measurements was reviewed by L. E. Peterson (University of California, San Diego), while a theoretical overview was given by R. Ramaty (NASA/Goddard Space Flight Center). Both speakers mentioned the detection of spectral lines in transient (burst) events. Those of 19 November 1978 and 5 May 1979 exhibited a feature at 0.4 MeV which is believed to be gravitationally redshifted positron-annihilation radiation, probably from the vicinity of a neutron star. G. Vedrenne (Centre d'Etude Spatiale des Rayonnements, Toulouse) described how the accuracy of locating bursts by triangulation had been improved (down to 1 arc min), using the long baselines available from interplanetary spacecraft such as Helios, Pioneer Venus, Venera and ISEE-3. However, no firm conclusion on the nature of burst sources could be drawn from the distribution of their locations, nor from the burst size (log N — log S) distribution.

Gamma rays of energy greater than 10^{11} eV can be detected at ground level by virtue of the Cherenkov light from the small air showers they generate in the Earth's atmosphere. K. E. Turver (University of Durham) and T. C. Weekes (Smithsonian Institution, Mount Hopkins Observatory) described recent developments in this field and emphasized the possibility of extending the technique to lower energies using multi-element detector arrays. Of the sources already detected, new results on Cygnus X-3 were presented by A. A. Stepanian (Crimean Astrophysical Observatory) and N. A. Porter (University College, Dublin). Reviewing investigations of pulsars, B. V. Sreekantan (Tata Institute for Fundamental Research, Bombay) remarked especially on the results from Ootacamund, where pulsed emission from PSR 0531 + 21 had been detected in February 1977, but despite increased sensitivity, not in the succeeding two winters (B. N. Bhat *et al. Astr. Astrophys.* **81,** L3; 1980). There was some speculation as to whether this variability might be related to a change in the 50–3,000-MeV light curve which COS-B had detected between 1975 and 1979 (presented on behalf of the Caravane Collaboration by R. D. Wills, Space Science Department of ESA).

Future prospects for gamma-ray astronomy were reviewed by C. E. Fichtel (NASA/Goddard Space Flight Center). In the next decade satellites such as the Soviet/French 'Gamma-1' and NASA's

Gamma-Ray Observatory should carry experiments which will have over an order of magnitude greater sensitivity than those flown so far while in some parts of the energy range substantially improved energy and angular resolution will be achieved. Such experiments should greatly enhance our knowledge of several astrophysical phenomena especially those associated with compact objects, astrophysical nucleosynthesis, galactic structure, the origin of cosmic rays, active galaxies and universal matter–antimatter symmetry. Meanwhile the meeting learned from R. D. Wills (Space Science Department of ESA) that COS-B was still recording good data after more than 5 years in orbit and that ESA's Science Programme Committee had recommended the continuation of its mission into 1981. □

Diffusionless reactions and crystal engineering

from J. M. Thomas

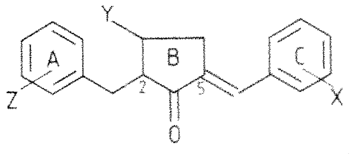
Diffusion, which is the spontaneous kinetic drift of atoms, ions and molecules, is a phenomenon so inextricably mingled with a wide range of chemical phenomena that it is difficult to imagine that there could be a class of chemical transformation in circumstances where even the idea of diffusion is superfluous. The migration of ions in solution or in solids, the dissolution of an electrode in an electrolytic cell, the transport of reactants to, and products from the surface of a heterogeneous catalyst are all well known examples of chemical processes in which diffusion plays a dominant role. Indeed there are many kinetic situations — the recombination of iodine atoms in the gas phase is a renowned example — where the diffusion of the reactants is rate-limiting. Under which set of circumstances, therefore, is diffusion of such little consequence?

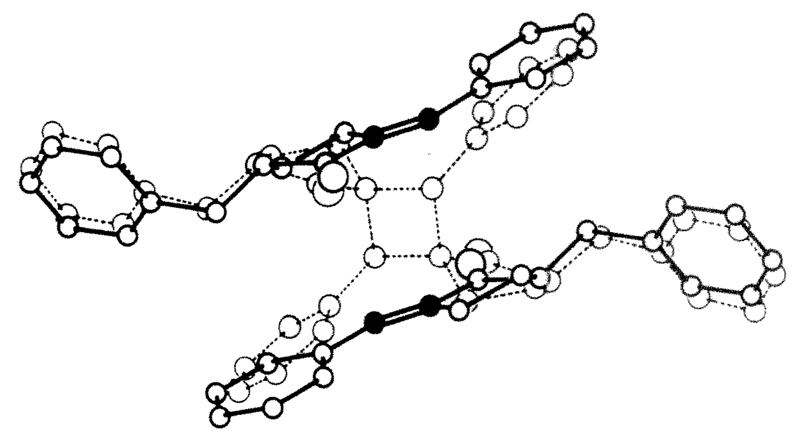
It is now clear that very many highly efficient and selective chemical reactions may proceed smoothly over a time scale of minutes or hours *in the solid state* without the need for prior diffusive motion. So frequently has it been remarked that chemical reactions are sluggish in solids because diffusion in the solid state is itself a very slow process, that it often comes as a surprise to discover that crystals of certain organic molecules can be induced to react rapidly, and in a preordained fashion, even at cryogenic extremes. The secret is to design these organic molecular crystals — to 'engineer' them — in such a way as to pack together potentially reactive monomer units which can subsequently be 'compelled' to undergo preferred reactions, which entail no diffusion but merely minor reorganization — a slight rotation or a subtle shift of part or all of the reactant molecules. Such reactions, which are termed topochemical, yield clean products, the chemical nature and crystallinity of which are governed more by the molecular environment within the parent crystal than by the intrinsic reactivity of the molecule.

Crystal engineering consists essentially of selecting molecules of a given class and functionality according to their size, shape and stereochemistry. They are then 'persuaded' to crystallize into certain desired crystallographic space groups; and within those crystals, by appropriate stimulation — UV irradiation, for example — diffusionless, intermolecular reactions are allowed to proceed.

Many aspects of this new approach to synthetic chemistry are an echo of the past. Kohlschutter (*Z. anorg. allg. Chem.* **105**, 121; 1918), the first to use the term topochemistry, realized that certain host crystals, notably graphite, dictate the degree of topotaxy associated with a solid-state reaction. Topotaxy refers to the mutual relationship between the unit cell axes of the daughter and parent crystals — in this case the graphite intercalates (for example, graphite–ferric chloride or potassium graphite) and the graphite, respectively. The late Gerhardt Schmidt, who was amongst the first to talk of crystal engineering, along with his associates at the Weizmann Institute, made many noteworthy contributions to this field (see Schmidt *Pure appl. Chem.* **27**, 647; 1971; Cohen and Green *Chem. in Britain* **9**, 490; 1973; and Thomas *Phil. Trans. R. Soc.* **A277**, 251; 1974). They and others have shown how various tactical substitutions in a molecular framework can be used as a steering device for preferred crystallization of a given desired crystal structure. The same approach has proved successful in persuading certain diolefins to crystallize with photoreactive rather than photostable structures, an approach which, in turn, has led to the solid-state synthesis of optically active molecules and many other novel products (Nakanishi *et al. Proc. R. Soc.* **A369**, 307; 1980).

Recently the delicate interdependence of crystal structure and reactivity in a family of related molecules derived from the skeletal framework shown below has been traced (Jones, Nakanishi, Theocharis and Thomas *J. chem. Soc. Chem. Commun.* 610; 1980). Various substitutions for X, Y and Z in the rings C, B and A were made and the photoreactivity of the monomer ascertained. The nature of the molecular packing was determined from the X-ray structure of each monomer crystal. It transpires that when the product (dimer) molecule occupies a similar volume within a crystal, and has a closely similar shape, as an adjacent pair of monomer molecules (an incipient dimer), single-crystal → single-crystal chemical transformation (without phase separation) can take place. In the figure below the adjacent molecules 1 and 2 (see framework with X, Y, Z all = H; this compound is 2-benzyl-5-benzylidene-cyclopentanone), which together constitute an incipient dimer, can undergo very minor movements at their peripheries during the course of a





Two neighbouring molecules of monomer (in which bonds are drawn with full lines) are so disposed with respect to one another in the 'engineered' crystal that they readily link up when irradiated with UV light to form a dimer. The four-membered cyclobutane ring (dotted bonds) is formed from the pairs of carbon atoms (shaded) linked originally by ethylenic bonds. Note how little the peripheral atoms (the benzene rings) move during this diffusionless reaction.

J. M. Thomas is Professor and Head of the Department of Physical Chemistry at the University of Cambridge.

0028-0836/81/080633-02$01.00

photodimerization that converts the doubly bonded carbon atoms (shaded) into a cyclobutane ring. In this crystal, monomer molecules pack so closely to one another — the ethylenic plane-to-plane distance is only 3.80Å — that dimerization proceeds freely to completion within the crystal matrix over a period of several hours.

Such changes are of considerable theoretical interest in that they permit, in principle, the atomic rearrangements to be monitored directly (at the diffusionless extreme) during the course of chemical reaction (Nakanishi, Jones, Thomas, Hursthouse and Motevalli; in the press). But such transformations have a wider relevance. New avenues of solid-state synthesis are opened up, by capitalizing on the idea that a potentially labile guest, when incarcerated within the well defined cell created by the crystal — be it of the pure material or of a host environment into which the guest has been buried on crystallization — has few options open to it. Through the agency of an externally applied stimulus, such as UV irradiation, the guest can to good advantage be converted into a more 'agreeable' state and then liberated (by dissolution for example) for appropriate utilization.

The sequential acts of molecular imprisonment and release, when prisoner and prison are carefully matched, can clearly be used to considerable advantage. Recent reviews (see Thomas *Pure appl. Chem.* **51**, 1065; 1979; Green, Lahav and Rabinovich *Acc. chem. Res.* **12**, 91; 1979) display the extent to which progress has been made in this direction. □

Habitat and the spread of rabies

from P.J. Bacon and D.W. Macdonald

AN international workshop on rabies, habitat classification and fox populations was held at Oxford recently*. As the behaviour of vectors of rabies, most notably the red fox, *Vulpes vulpes*, is known to be affected by the habitat and as the epizootiology of rabies appears to be affected by landscapes on both a fine and a gross level, it was hoped that a meeting of zoologists, epidemiologists and geographers could spark off new approaches to understanding and combatting a disease which has so far thwarted most attempts at control.

The first problem to be tackled was the classification of habitats. A robust method of describing landscapes is necessary not only for understanding the way foxes and rabies behave in differing habitats, but also for extrapolating from small study areas to the continental scale at which disease control must work. R.G.H. Bunce (Institute of Terrestrial Ecology, UK) described a classification method that was intended, in part, to enable the findings of detailed ecological studies at specific sites to be generalised to the whole of Britain. A wide variety of ecological parameters, such as soil profiles, natural vegetation and agricultural crops, determined by field-survey, are highly correlated to topographic features that can be measured from Ordnance Survey maps: these correlations can then be used to predict the factors from map measurements of areas not surveyed. The method accurately predicts, for example, acreages of various crops and potential primary productivity and an attempt is being made to produce a map of potential (that is, 'carrying-capacity') fox densities for the whole of Britain (Macdonald, D.W., Bunce, R.G.H. & Bacon, P.J. *J. Biogeography* in the press). The predictions are supported by the known fox densities in some areas although they cannot yet incorporate local variations in human hunting pressure. P.J.A. Howard, (Institute of Terrestrial Ecology, UK) reviewed methods of classification (that is categories concerned with natural divisions within the data) that were appropriate for habitat description; and concluded that while a suitable stratification into some type of category was desirable to permit efficient sampling of habitats, the aim of prediction might be better served by statistical methods using regression of the original data on variates important to the aspects being predicted. Thus, for example, it might be better to compare fox densities to measures of the landscape (for example, percentage of woodland, percentage of cereal crop) rather than to ordinal categories into which the landscape had been classified (for example, 'woodland', 'arable land' and so on). His recommendations received support from U. Emanuelsson (University of Lund) predictions of bird breeding densities in Swedish Lapland using formulae derived from regression of known densities against measures of landscape, such as area of woodland, altitude, and so on.

The aspirations of the workshop were well illustrated by quantitive investigations of the relations between landscapes and rabies spread. Using data on case-occurence made available by L. Andral (Centre d'etudes sur la Rage, France), F. Ball (University of Oxford), looked for relations between the velocity of the front wave of rabies to a set of data (collected by himself and P.J. Bacon) describing the habitats in which those cases occurred. Ball posed three questions (a) how does the behaviour of the front wave of rabies epizootic vary with habitat, (b) is infection better described by nearest neighbour models, that is with one resident fox passing the disease to its territorial neighbours and its own group members, or by dispersing fox models, that is, those taking into account the movements of many kilometres made by young male foxes, and (c) would a knowledge of habitat effects increase one's ability to predict the likely spread of the disease? He demonstrated that variations in front wave velocity can be linked to measures of the landscape, which correlate with fox densities. Examples of important measures are altitude (there are few foxes on mountain tops), railway lines (which follow fertile valleys and hence perhaps represent ribbons of high fox density, while also channeling fox movements) and vineyards (which are associated with broken hilly terrain suitable for foxes — indeed, biblical foxes often ate grapes and present day ones certainly eat blackberries). Map-data can thus be used to explain a significant amount of the historical variation of front-wave velocity in France, and similar measurements in areas in advance of the wave-front might have predictive value.

J. Ross (Imperial College London), applied B. Sayer's (Imperial College London), approach to the French data supplied by L. Andral and demonstrated the effects of rivers and motorways in diverting the path of the epizootic. Neither are readily crossed by foxes so movements tend to be along, not across them. From the case incidence data she drew trajectories of the disease front as it spreads across France month by month. When these trajectories are superimposed upon a geological map it is evident that the disease has followed a belt of limestone running south west across France. It seemed plausible that the rich soil of this limestone country was mirrored, through high primary productivity, in high fox populations. She also showed that rabies spread through areas of different landclasses (as described by Ball) had different temporal characteristics. These differences seemed largely associated with the presence or absence of upland pastures — habitat which might be good mouse-hunting country for foxes.

P.J. Bacon is at the Institute of Terrestrial Ecology, Merlewood Research Station, Cumbria and D.W. Macdonald is in the Department of Zoology, Oxford.

---

*The *Workshop in Rabies Spread, Habitat, Classification, and Fox Populations* was held at Keble College, Oxford from 15 to 19 September 1980. The sponsors were the Nuffield Foundation and the Insititute of Terrestrial Ecology. A full report of the meeting (with references and a list of participants) will be edited by the organisers and will be obtainable from The Librarian, Institute of Terrestrial Ecology, Merlewood Research Station, Grange over Sands, Cumbria LA11 6JU.

0028-0836/81/080634-02$01.00

Considerable debate revolved around the extent to which sophisticated analyses could be extended, considering the uncertainties of rabies surveillance. The reporting of cases is much more efficient along the epizootic front than in enzootic districts where familiarity soon produce negligence. Rather dismaying disclosures about the consistency of the data on which statisticians must work were endorsed in a devastating analysis by A. Wandeler (University of Berne) of the biases in the hunting figures frequently employed as indirect indicators of fox numbers. Factors such as the phase of the moon affect hunters' behaviour, and hence the bag records! It was widely agreed that every effort should be made to standardise the recording of rabies incidence, even if only in sample districts.

Students of fox ecology were not the only biologists present, since the principles underlying analyses of habitat utilisation are widely applicable. H. Kruuk, (Institute of Terrestrial Ecology, UK), showed how the dispersion of habitat patches (and hence available food in the form of earthworms) determined the size of badger *(Meles meles)* territories and their local population density. Earthworms can only be captured on warm and humid nights when they are tempted onto the surface. From night to night, with shifting wind direction for example, different fields will temporarily become bountiful foraging sites. Kruuk argued that badger territories must contain sufficient foraging sites so that at least one will yield worms irrespective of changes in the wind. Territory size, and ultimately population density, is thus a function of the dispersion of potential earthworm patches — a factor that can to some extent be predicted from maps. When the meeting learnt from Wanderler (University of Berne) that badgers had been more involved than previously thought in rabies spread in Switzerland it was realised that these findings were of practical as well as theoretical importance. Kruuk's findings in Scotland could be compared with those of I. Lindsay and D. Macdonald (University of Oxford). They had examined the habitat components of badger territories in Buckinghamshire and found, for example, that territory size varied with the acreages of cereal land they encompassed. These arable crops are unimportant in the badgers' diet and can be interpreted as 'dead space' in the badgers' territories. S. Harris (University of Bristol), found urban-dwelling badgers living at extraordinarily high densities. Indeed, the participants collectively blanched at the prospect of rabies control in urban areas, because it was apparent that the densities of both wild and domestic vectors are extremely high and almost unassailable by conventional control methods. The highest fox densities recorded were from suburbs where Macdonald has found home ranges as small as 10 hectares. In the same habitat foxes were living in social groups — another factor which doubtless would effect rabies epizootiology.

Two schools of thought emerged on the most useful way to proceed — one was that fox population dynamics were so complicated that effort might most profitably be directed to seeking broad relationships between general features of the landscape and rabies spread, while the opposing view was that the data on rabies spread were so coarse and inconsistent that direct and detailed study of foxes was more likely to yield a better understanding of the factors affecting the pattern of rabies spread. In either case, concensus was reached that the most crippling obstacle was our ignorance of the behaviour of rabid foxes and the extent to which it differs from that of healthy animals. □

100 years ago

The Singular Methods of Travel the Wagtail adopts to Cross the Mediterranean Sea.

One evening we were sitting at the foot of the pyramid of Cheops, sipping our cup of fragrant Mocha and in jolly conversation, rolling up clouds of blue smoke from our Korani cigarettes. We were waiting for the sinking of the sun to make our return to Cairo. The deep silence of the surrounding desert possessed something uncommonly solemn, only now and then disturbed by the cry of the hoarse fishhawks far above us. Still higher the pelicans were grandly circling. Their flight, though heavy when seen from anear, possess a majesty in the distance attained by no other bird. Right before us several wagtails were hopping around and 'tilting'. They were quite tame, and flew restlessly hither and thither. On this occasion I remarked, 'I could not quite understand how these birds could make the long passage of the Mediterranean.' Sheik Ibrahim heard this from our interpreter. The old Bedouin turned to me with a mixture of French and Arabic as follows, which the interpreter aided us to fully comprehend:-

" 'Do you not know, Hadretch (noble sir), that these small birds are borne over the sea by the larger ones?'

"I laughed, as did our friends; for at first we thought we had misunderstood him; but no: the old man continued quite naturally:-

" 'Every child among us knows that. These little birds are much too weak to make the long sea journey with their own strength. This they know very well, and therefore wait for the storks and cranes and other large birds, and settle themselves upon their backs. In this way they allow themselves to be borne over the sea. The large birds submit to it willingly; for they like their little guests, who by their merry twitterings help to kill the time on the long voyage.'

"It appeared incredible to us. We called to a pair of brown Bedouin boys, pointed out the wagtails to them, and inquired:-

" 'Do you know whence come these small birds?'

" 'Certainly,' they answered. 'The Abu Saad (the stork) carried them over the sea.'

"At supper, in the Hôtel du Nil, I related the curious story to all present, but naturally enough found only unbelieving ears.

"The only one who did not laugh was the Privy Councillor Heuglin, the famous African traveller, and, excepting Brehm, the most celebrated ornithologist of our time for the birds of Africa. I turned to him after the meal, and inquired of his faith. The good royal councillor smiled in his caustic way, and with a merry twinkle remarked: 'Let the others laugh: they know nothing about it. I do not laugh, for the thing is known to me. I should have recently made mention of it in my work if I had had any strong personal proof to justify it. We must be much more careful in such things than a mere story-teller or novel-writer; we must have a proof for everything. I consider the case probable, but as yet cannot give any warrant for it.'

"My discovery, if I may so call it, I had kept to myself, even after Heuglin had thus expressed himself, and would even now maintain silence on the subject had *I not* recently discovered a new authority for it."

I read lately in the second edition of Petermann's great book of travels the following:-

"Prof. Roth of Munich related to me in Jerusalem that the well-known Swedish traveller, Hedenborg, made the following interesting observation on the Island of Rhodes, where he stopped. In the autumn tide, when the storks come in flocks over the sea to discover them. Once he followed a flock of storks, and as they lighted he saw small birds fly up from their backs, which in this manner had been borne over the sea. The distance prevented him from observing to which species of singing birds they belonged."

We regret that the Lords should have thrown out the Bill on Tuesday for the Opening of Museums and similar places on Sundays. As the *Times* very well puts it:— "The gravity of the question is that London has in its midst people to whom anything of the nature of intellectual toil — and prolonged sight-seeing is of that character — is essentially irksome. But they are human beings, and not lost to all salutary influence. It would be folly to despair of making the Sunday more tolerable than it is to them. Our climate does not often admit of men and women sitting out of doors talking or listening to elevating music. Some substitute must be found to put on on equality with the people of more sunny lands. It is the task of true friends of the working classes to suggest means by which, without any revolution in national ideas as to the sacredness of Sunday, they may be enabled to taste those simple and primitive pleasures — for example, the pleasure of pure repose of mind and body, or that of hearing music — which all, even the untutored, can enjoy.

The expanding science of photobiology

from John Jagger

Photobiology is concerned with the vast range of actions of nonionizing radiations on biological systems — from photolysis of simple molecules in pure solution to the effects of sunlight on human skin and problems of world food production through photosynthesis. The common thread that held the five hundred participants at the recent International Photobiology Congress at the Louis Pasteur University, Strasbourg, together is an interest in the fundamental biophysical mechanisms involved in the interactions of light and living matter. In line with this orientation is the increasing use of sophisticated physical techniques, such as picosecond dye-laser pulse studies of electron energy exchange between chlorophyll pigments in chlorophyll–protein complexes (J. Breton and G. Paillotin, Centre d'Etudes Nucléaires de Saclay; N.E. Geacintov, New York University), and picosecond kinetic measurements at liquid-helium temperature of proton translocation in the retinal molecule (M. Chabre, Grenoble).

Reversible photochemical reactions are often used by biological systems to sense changes in the environment. The most obvious and certainly the most sophisticated such system involves the protein rhodopsin pigments used in **animal vision**. Photoisomerization of the retinal prosthetic group of rhodopsin leads to an alteration of the receptor cell membrane potential, but the intermediate steps are not understood. Since the cell membrane is not connected to the disks that contain the rhodopsin, there must be a diffusible transmitter, and this is now believed to be cyclic GMP, rather than the previously proposed calcium ion (M. Chabre, Grenoble). It is proposed that rhodopsin floats in a fluid membrane and, on photoexcitation, interacts with an enzyme chain controlling cyclic GMP levels. There is evidence that the site of interaction of rhodopsin with membrane enzymes is remote from the retinal itself, which implies that there is an overall conformational change of the whole rhodopsin molecule. Support for this picture comes from the findings of H. Shichi and R.L. Somers (National Eye Institute) that purified rhodopsin illuminated *in vitro* activates a purified GTPase; this results from formation of a protein–rhodopsin complex and does not require a membrane environment.

Another important reversible photoreaction used by biological systems for sensory purposes is the **phytochrome system** of plants. H. Smith (University of Leicester) discussed the role of phytochrome in the natural environment. Light penetrating a plant canopy is enriched in far-red wavelengths (700–750 nm), because of absorption of other wavelengths by chlorophyll. This alters the phytochrome photoequilibrium, thus permitting the plant to detect the amount of canopy shade, and to react accordingly — either by growth out of the shaded area or by changing leaf and chloroplast development and metabolism to adapt to the shade regime. However, it is still not clear whether this detection depends on the ratio of the red and far-red forms of phytochrome or on the amount of the far-red form present.

Extremely sensitive **bioluminescence assays** were described by A.M. Michelson (Institut de Biologie Physico-Chimique, Paris), based upon the fact that clam luciferases behave like peroxidases, producing superoxide radical anion, which then causes the clam luciferin to luminesce. Such systems permit estimation of femtogramme quantities of peroxide, and exquisitely sensitive estimations of hydrogen peroxide, superoxide radical anion, and enzymes like peroxidase and superoxide dismutase. In enzyme assays, turnover of the enzyme provides an effective amplification of the light. Such techniques have also been used for estimation of antibodies bound either to such enzymes or to luciferases.

In the area of basic mechanisms in **ultraviolet photobiology**, progress has been made in the study of lethal effects of near-UV radiation (300–380 nm), which is present in sunlight at the surface of the Earth. M.J. Peak and J.G. Peak (Argonne National Laboratory) have shown that there is a 365 nm maximum in the action spectrum for induction of single-strand breaks in purified bacterial transforming DNA irradiated *in vitro*. These breaks are primarily true breaks (as opposed to alkali-labile bonds) and generally require oxygen; they might explain the small plateau observed at this wavelength in action spectra for killing of *E.coli* in air. However, work by A.G. Miguel and R.M. Tyrrell (Federal University of Rio de Janeiro) indicates that single-strand breaks are very readily repaired and are therefore probably not the major lethal lesion. Similar arguments have previously eliminated pyrimidine dimers from consideration. Thus, the primary near-UV lethal lesion in wild-type bacteria remains to be identified. Whatever the damage, one of its first manifestations appears (S.H. Moss and K.C. Smith, Stanford University School of Medicine) to be an altered cell membrane, which makes a significant contribution to the killing of cells plated on minimal medium.

An inducible repair system for near-UV lethal damage in *E. coli* has been found by J. Peters and J. Jagger (University of Texas at Dallas). The system accounts for a large fraction of lethality in actively growing cells, and is distinct from the far-UV-induced SOS system. In related work, S. Menezes and R.M. Tyrrell have shown that repair systems inducible by far-UV (200–300 nm) radiation play a relatively minor role in the repair of near-UV damage.

Photomedicine was much in evidence reflecting a maturation of photobiology in its application to medical problems. Of great interest were developments in so-called PUVA therapy, which involves the treatment of skin lesions, such as psoriasis, by administering the dye *P*soralen (orally) and then irradiating with *UV-A* light (near-UV light in the range 320–380 nm). This therapy has been extremely effective in producing clearance and remissions. Unfortunately, there is concern that long term PUVA may act as a promoter of non-melanoma skin cancer, although this hazard has not prevented some 80,000 patients in all parts of the world from utilizing the therapy because the disease itself is so disfiguring. P. Vigny, D. Averbeck and co-workers (Institut Curie, Paris) have now found that a psoralen derivative, 3-carbethoxypsoralen, does not produce interstrand DNA cross-links, in contrast to the commonly used 8-methoxypsoralen, and the new compound shows therapeutic activity in mice without exhibiting carcinogenesis. Additional new isopsoralen derivatives that produce only monofunctional addicts in DNA have been synthesized by the Padua University group of G. Rodighiero. This is a happy development which opens the way to possible broad use of light-and-chemical treatments (photochemotherapy) of skin disorders.

A second area of great medical interest concerns the immunological rejection of UV-induced **skin cancers**, studied by M.L. Kripke and co-workers (Frederick Cancer Research Center, Maryland). Many UV-induced squamous carcinomas and fibrosarcomas are immunologically rejected when transplanted to normal syngeneic recipients, but grow progressively in immunologically deficient animals or animals that have been UV irradiated (including the animals in which they were originally produced). Kripke and co-workers have found that antigens produced during UV irradiation of the skin trigger the production of suppressor T lymphocytes, which in turn prevent an immunological rejection of the tumour. Langerhans cells (macrophage-like cells in the skin) may be involved in the initial events in this process. K. Wolff (Innsbruck University) pointed out that Langerhans cells show the highest susceptibility to UV damage of all skin cells, and that UV

abolishes their immunological surface markers and abrogates their capacity to stimulate T-lymphocyte proliferation. E.C. DeFabo and F.P. Noonan (Kripke's group) have found that the wavelength maximum for depression of contact sensitivity in mouse skin is at about 270 nm, which may reflect absorption by urocanic acid, a metabolite of histidine, which accumulates in the skin where it cannot be further metabolized. Urocanic acid, incidentally, has been proposed by J.A. Parrish (Massachusetts General Hospital) to act as a natural photoprotection (light-screening) agent, which is partially removed when skin is washed, explaining an observation first made by Jacopo Beccari in 1744 that his hands fluoresced better in sunlight after being washed.

Finally, a disturbing medical development is the recent rise in the incidence of malignant melanoma: world mortality rates have approximately doubled in the last fifteen years. It is not generally recognized that skin cancers are the most common malignant tumours of man. Although the overall mortality is less than 5%, malignant melanomas show about a 40% mortality, and they represented about 1% of all cancer deaths in 1970. The recent increase in melanoma incidence is generally attributed to increased sun-exposure habits, although it is possible that there is some kind of synergism between UV radiation and environmental toxic chemicals, as in the observations of P.D. Forbes and co-workers (Temple University Health Sciences Center) that concurrent exposure to retinoic acid and UV stimulates tumour development. Effective topical sunscreens are thus of great importance, and the need for international standardization of sunscreen efficacy was discussed in a Round-Table held at the congress.

Photobiology has become a very active discipline that is now rapidly maturing. Sophisticated physical and chemical techniques are being applied, and significant advances in fundamental knowledge are being made. It is playing an increasingly important role in medicine. All this comes as no surprise to the photobiologists, who share the view of Isaac Asimov that "The Earth is bathed in light from the Sun, and one could scarcely think of a more important single fact than that." □

Antisickling drugs and water structure

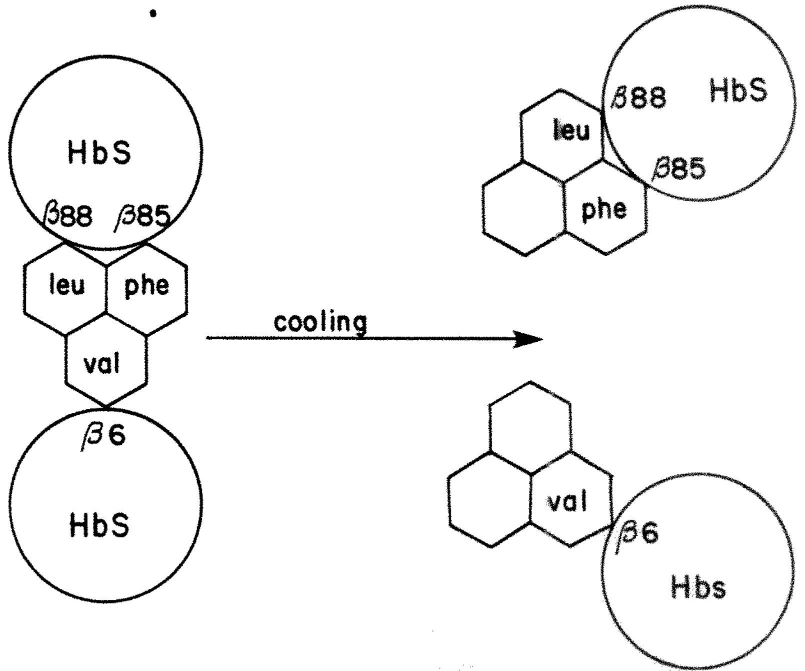
from Ruth and Reinhold Benesch

In sickle cell anaemia the substitution of a valine for a glutamic acid in the β chain of the normal haemoglobin molecule causes a polymerization of the deoxygenated sickle cell haemoglobin. In order to design drugs to prevent aggregation of the sickle cell haemoglobin (HbS) an understanding of the molecular mechanisms involved is obviously required[1,2]. Stillinger's[3] recent article, *Water Revisited*, has led us to suspect that the hydrophobic class of sickling inhibitors may act on water structure rather than by stereospecific interaction with HbS itself. Stillinger points out the analogy between hydrophobic interaction and the anomalous behaviour of supercooled water. Water is described as a random three-dimensional network of hydrogen bonds in which are embedded relatively bulky, unstrained hydrogen bond polyhedra. The concentration of these polyhedra increases as the temperature is lowered. The attractive force between them and their consequent 'clumping' is responsible for some of the unusual properties of supercooled water. When a non-polar solute is dissolved in water, the random network of hydrogen-bonded water molecules reorganizes around it to form very similar bulky convex polyhedra which only differ from the empty ones found in supercooled water by the presence of the hydrophobic molecule in their centre. The attraction between these 'filled' convex polyhedra provides the physical basis for the 'hydrophobic bond'.

A characteristic feature of hydrophobic interactions is their unusual temperature dependence, that is, they become weaker as the temperature is lowered. This can readily be explained in terms of the picture provided by Stillinger. Since lowering the temperature will increase the concentration of empty polyhedra, the probability of a filled one interacting with an empty one, rather than with another filled one, will increase and the attraction between the hydrophobic residues will weaken with decreasing temperature.

When sickle cell haemoglobin polymerizes it forms a gel that 'melts' as the temperature is lowered. Crucial side-to-side contact between strands of HbS molecules in the crystal (and therefore presumably also in the fibres formed by the haemoglobin) was shown to exist between valine β6 of one molecule and phenylalanine β85 and leucine β88 of the neighbouring one[4]. If this bond can now be regarded as the result of the attractive forces between hydrogen bond polyhedra containing these residues (see the figure), then it should be broken as the temperature is lowered because of competition by the empty water polyhedra as their concentration increases with decreasing temperature.

An analogous mechanism would also account for the well documented inhibition of HbS polymerization by a variety of compounds containing hydrophobic residues[5-9]. There is no clearcut relationship between the structure of these inhibitors and the known geometry of the sites containing valine β6 and phenylalanine β85



Depolymerization of deoxy-HbS on cooling: In this schematic diagram the hexagons represent the hydrogen bond polyhedra discussed in the text.

and leucine β88. Thus, for example, the D isomeric forms of aromatic amino acids are as active as the L isomers[10]. This supports the hypothesis that the inhibition of polymerization by these compounds is brought about by competition between the water polyhedra filled with the small hydrophobic molecules with those attached to the protein, rather than a direct interaction between the hydrophobic residues and the protein which should be stereospecific. This picture would also explain why attempts to increase the effectiveness of hydrophobic antisickling agents by structural modification have met with relatively little success. □

Fifty years of Slough's ionosphere

from Henry Rishbeth

ON 11 January 1981 the 'noon run' of the Slough ionosonde marked with due ceremony the fiftieth anniversary of routine ionospheric sounding. An ionosonde is a kind of swept-frequency radar and radar developed from the experimental studies of the ionosphere that were conducted at Slough and elsewhere in the twenties and thirties. This work followed from the basic experiments of 1924–25 in Britain (E. V. Appleton and M. A. F. Barnett *Nature* **115**, 333; 1925) and in the US (G. Breit and M. A. Tuve *Nature* **116**, 357; 1925) that conclusively proved the existence of radio-reflecting layers in the upper atmosphere. It was Watson-Watt at the Radio Research Station (RRS), Slough (now the SRC Appleton Laboratory) who coined in 1926 the term 'ionosphere' (G. W. Gardiner *Nature* **224**, 1096; 1969). Years later, the output of analysis and interpretation based on Slough data gave rise to the unofficial definition of the ionosphere as 'the part of the atmosphere vertically above Slough'.

To promote scientific understanding of the ionosphere and to meet the growing needs of radio communications, systematic data were needed. RRS publications contain some h'–f data on apparent reflection heights (h') at different radio frequencies (f) obtained in 1930. However, the most important data on the ionospheric layers (E, F1 and F2 layers, respectively at heights of around 100, 180 and 250–350 km) are their 'penetration' or 'critical' frequencies (fE, fF1, fF2) as measured by a swept-frequency sounder. The series of critical frequency data began at noon on 11 January 1931 (a Sunday, like its fiftieth anniversary) and has continued with few breaks to the present day. Initially only fE was recorded, on ninety days in 1931. Tabulated fF2 data start on 19 December 1931, but it was not until 20 September 1932 that the long series of daily values was initiated, the first 'noon run' for which all three parameters fE, fF1, fF2 are preserved being on 23 September 1932. Hourly soundings — which are now made routinely — were made only for three 24-hour periods during 1931; from these data it appears that the initial value at 1200 GMT on 11 January 1931, namely 2.1 MHz, may be about 15–20 per cent low in comparison with neighbouring values. Furthermore, it was then also possible to record fE at night to values as low as 0.7 MHz: this could not be done nowadays with normal ionosondes in England, owing to the prevalence of radio broadcast interference (R. W. Smith, personal communication). Today, data from the Slough ionosonde are distributed to numerous users on schedules to meet their particular needs, which may include long-term 'predictions' of ionospheric conditions or short-term 'forecasts' of disturbances. Some users, including the BBC, Marconi's and Jodrell Bank, receive noon 'critical frequency' data by telex each working day. It is interesting that the largest value of fF2 ever recorded at Slough occurred in the present solar cycle, namely 17.2 MHz at 1300 and 1400 GMT on 15 December 1979.

Other long series of ionospheric data have been produced at Huancayo (Peru), Watheroo (Western Australia) and Washington (DC). By the start of the International Geophysical Year of 1957–58 about 140 ionospheric observatories were in operation, many of which have continued to this day, thereby creating global data sequences extending over two sunspot cycles. This well organized scientific resource is available to researchers through the World Data Centre at Slough, and corresponding Centres in Boulder (Colorado), Moscow and Tokyo, established at the start of the IGY.

What of the future? Following the merger with the SRC Rutherford Laboratory, Appleton Laboratory work is being transferred away from Slough. Current thinking is that an ionosonde should remain permanently in the Slough area. Possibilities being considered for the future are the automatic read-out of data to the merged laboratories' site at Chilton, with dial-up access by users both to past data and to the up-to-the-hour state of 'the part of the atmosphere vertically above Slough'.

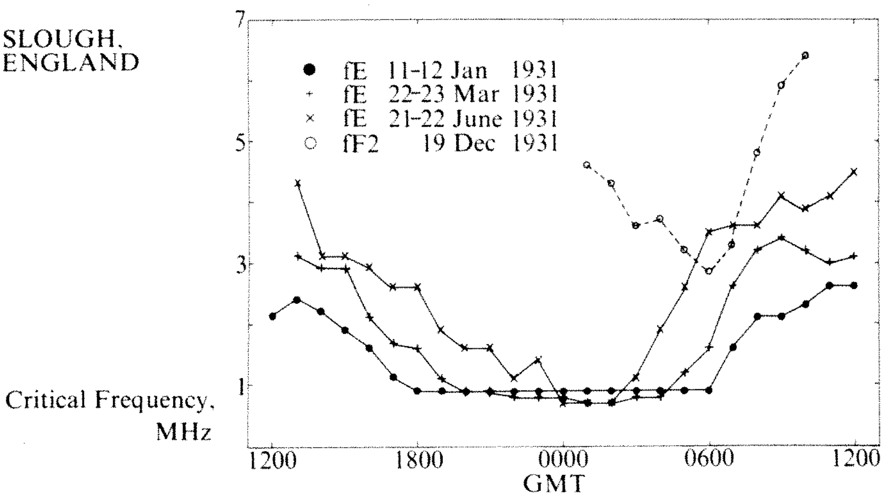

Fig. The four sequences of hourly critical frequency data recorded at Slough (51½°N, ½°W) during 1931
The values refer to the 'ordinary' magnetoionic component. Some of the fluctuations in fE are probably due to sporadic E.

Henry Rishbeth is at the Rutherford and Appleton Laboratories, Slough, UK.

ARTICLES

Stable isotope composition of benthic foraminifera from the equatorial Pacific

Edith Vincent, J. S. Killingley & W. H. Berger

Scripps Institution of Oceanography, La Jolla, California 92093

When ranked according to deviation from isotopic equilibrium, deep-sea benthic foraminifera exhibit no correlation between the rankings for oxygen and for carbon. Both rank sequences are stable from east to west in the equatorial Pacific (fertility-independent) and from Glacial to post-Glacial (time-independent). Records for the past 15,000 yr suggest marked changes in deep-sea circulation during this time interval.

STABLE isotopic compositions of benthic foraminifera reflect bottom water conditions. The $^{18}O/^{16}O$ ratio of the calcium carbonate in their shells is strongly dependent on the temperature and oxygen isotope composition of the ambient water, whereas the $^{13}C/^{12}C$ ratio is related to the carbon isotopic composition of the total dissolved inorganic carbon. Oxygen isotopic changes in benthic foraminifera from deep-sea sediments, first used in Emiliani[1,2] to reconstruct bottom water changes, have been used to reconstruct Pleistocene variations in Atlantic bottom water temperatures[3,4]. But changes in the carbon isotopic composition of benthic foraminiferal tests can also aid palaeoceanographic interpretations[5].

Although the initial assumption that all deep-sea benthic foraminifera deposit their shells in equilibrium with seawater[6] is incorrect[7-10], it is thought that for oxygen isotopes, deviation from equilibrium is small in some species[11,12], and that more substantial deviations of other species are constant and can be corrected for by adding a constant value to the measured $^{18}O/^{16}O$ ratio[5,13-19]. We show here that the ranges of variation within individual species and of isotopic differences between species are of the same order of magnitude as isotopic changes commonly recorded in Pleistocene sediments. Thus, our results impose limits on the significance of downcore isotope records based on single-species analyses, especially if small samples with few specimens are used.

Materials and methods

Benthic foraminifera from western and eastern equatorial Pacific sediments, recovered by box coring during Scripps Institution of Oceanography Expeditions Eurydice (ERDC, 1975) and Pleiades (PLDS, 1976) respectively, were analysed. Sedimentation patterns in the two areas have been described elsewhere[20,21]. They are characterized by relatively high sedimentation rates and high carbonate content (Table 1). Carbonate content in the east (PLDS) is lower than in the west (ERDC), largely because of high silica content in the eastern high fertility area. The higher fertility in the east is also reflected by the rate of sedimentation and a high ratio of *Neogloboquadrina dutertrei* to *Pulleniatina obliquiloculata* (Table 1), the former planktonic species being associated with upwelling[22]. For the present study, dissolution effects are not important above 3,000 m depth, and probably did not affect our results significantly, even in the two deepest cores.

We sampled the surface sediments in these box cores as well as a deeper level in Box-core ERDC-92 dated at 16,000–17,000 ^{14}C yr (ref. 23). All benthic foraminifera larger than 250 μm in each sample were selected and 150–400 specimens per sample were thus isolated. Of these specimens, 10 species were abundant enough to run replicate isotopic analyses (Table 2). Over 100 analyses for both oxygen and carbon were performed. Typically 4–7 specimens with a total weight of at least 0.5 mg were used for each analysis. Samples were cleaned ultrasonically to remove fine particles from inside the foraminiferal tests. Isotopic analysis followed standard procedures[24]. Benthic foraminifera taxonomy followed that of Culp[25].

In Core ERDC-92 foraminifera were analysed from discrete size fractions (149–250 μm, 250–420 μm and >420 μm). No correlation of isotopic composition with size was detected, however, in contrast to the well-established size effect on isotopic composition in planktonic foraminifera[26].

Species abundances

The two most common benthic species in samples shallower than 3,000 m are *Planulina wuellerstorfi* and *Oridorsalis umbonatus*, which each comprise 10–20% of the total number of individuals in the calcareous benthic assemblage. Below 3,000 m, these species and *Nuttalides umbonifera* dominate the benthic assemblages (ERDC-135 and PLDS-66). Here *N. umbonifera* represents 12–13% of the calcareous benthic fauna, whereas it is absent in the shallower samples.

All other species analysed are less common and generally constitute <5% of the calcareous benthic fauna. *Uvigerina*, which is rare (<2%) or absent in all ERDC samples, is common in the PLDS-66 sample, making up 15% of the calcareous benthic fauna. The higher productivity of surface waters in the eastern region is presumed to cause an increased supply of food to the underlying benthos. Therefore we suggest that the abundance of *Uvigerina* indicates a region of high fertility. This

All specimens are >250 μm except *S. interrupta*, which is from the 149–250 μm size fraction. In each column the first number to the left is the mean δ value with respect to ‰ PDB; the number in parentheses is the number of analyses followed by the range *r* and by the standard deviation if more than three analyses were made; the last number, ro the right, is the Δδ value (the mean δ value minus the estimated equilibrium value).

* For present-day conditions the $^{18}O/^{16}O$ composition of calcite at equilibrium with ambient-bottom water was calculated using a palaeotemperature equation[44] and estimated temperatures[45] of 3°, 1.8°, 1.5° and 1.5 °C for ERDC 92, 123, 135 and PLDS 66, respectively. The isotopic composition of the bottom water was assumed to be −0.4 (PDB) (ref. 46).

† Present-day equilibrium $^{13}C/^{12}C$ composition of equilibrium calcite was estimated for the four core sites using reported fractionation relationships between calcium carbonate and dissolved bicarbonate[47]. Ambient $\delta^{13}C$ (PDB) values for bicarbonate were calculated as 0.15, 0.18, 0.25, and 0.25 for cores ERDC 92, 123, 135 and PLDS 66, respectively, from apparent oxygen utilization (AOU) to $\delta^{13}C$ relationships[13]. AOU values were obtained from reported temperature, salinity and dissolved O_2 data[45,48].

assessment is supported by its decreasing abundance in Box-Core ERDC-123 from Glacial to Holocene sediments (from 6% of the benthic calcareous assemblage to <1%) in parallel to other trends commonly associated with decreasing fertility: (1) a decreasing sedimentation rate (from 3 to 1.8 cm kyr^{-1}); (2) a decreasing *N. dutertrei*/*P. obliquiloculata* ratio (from >1 to 0.2); and (3) a decreasing benthic foram number (from ~30 to 10 benthic foraminifera larger than 250 μm g^{-1} of dry sediment).

Oxygen isotopes

Results of the oxygen analyses are given in Table 2*a*. Species are listed in the order of deviation from estimated equilibrium values, which for $\delta^{18}O$ in present day conditions range from 3.2 to 3.6‰, depending on the water depth of the core location (see Table 2*a*). Our comparisons are between species, between periods (ERDC-92, Holocene and Glacial), and between areas of low fertility in the west (ERDC) and high fertility in the east (PLDS). The disequilibrium ranking (greatest disequilibrium first) consists of two groups: 'low ^{18}O' and 'high ^{18}O'. The low ^{18}O group includes *N. umbonifera*, *L. pauperata*, *P. wuellerstorifi*, and *Favocassidulina favus*, which are clearly depleted in ^{18}O relative to equilibrium by around 0.5‰ in the ERDC samples. The high ^{18}O group contains *O. umbonatus*, *Siphouvigerina interrupta*, *Cassidulina subglobosa*, *Quinqueloculina auberiana* and *Uvigerina* spp., which have oxygen values close to equilibrium (for *Uvigerina* see ref. 5). *Hoeglundina elegans* is a separate case: its shell is aragonitic[27–29]. The equilibrium values for aragonite are not known for these low temperatures.

The grouping into low ^{18}O and high ^{18}O seems unrelated to time (column 1 compared with column 2) and with fertility (columns 1, 3, 4 compared with column 5). From the $\Delta\delta^{18}O$ values (the mean δ values minus the estimated equilibrium values) in Table 2*a* and Fig. 1*a*, it seems that there is a fertility effect on isotopic composition, because the degree of disequilibrium for oxygen increases from west to east. Compared with the eastern core (PLDS 66), the five benthic species shown for the western cores (ERDC) all contain a higher $^{18}O/^{16}O$ ratio and are closer to estimated equilibrium values. Moreover, between the western cores an increase in disequilibrium with increasing sedimentation rate is indicated, which in turn is related to fertility.

The large range in most of the replicate analyses makes it impossible to confirm that the amount of change in disequilibrium with fertility is species dependent.

Carbon isotopes

Results of the carbon analyses are given in Table 2*b*. Again, species are listed in the order of deviation from estimated equilibrium values, which range in $\delta^{13}C$ from 1.2 to 1.5‰, depending on the apparent oxygen utilization (AOU) in the water. The AOU indicates how much oxygen has been used to oxidize organic matter to produce additional CO_2 (with a $\delta^{13}C$ near −20‰)[26,30]. The ranking (greatest disequilibrium first) consists of four groups: 'super low ^{13}C', 'low ^{13}C', 'medium ^{13}C', and 'high ^{13}C'. The super low ^{13}C group includes *O. umbonatus* and *F. favus*, the low ^{13}C group includes *Uvigerina* spp., *S. interrupta*, and *C. subglobosa*, the medium ^{13}C group includes *L. pauperata* and *N. umbonifera*, and the high ^{13}C group is made up of *P. wuellerstorfi* and *Q. auberiana*. Again, the aragonitic *H. elegans* is anomalous, with very high $\delta^{13}C$ values.

The carbon ranking's apparent independence of the oxygen ranking, may indicate that at least two mechanisms of fractionation are involved which operate more or less independently to produce the 'vital effects' in oxygen and carbon isotopic compositions. As was shown for oxygen, ranks apparently are time- and fertility-invariant (columns 1 compared with 2; and 1, 3, 4 compared with 5). Comparison of the degree of disequilibrium for carbon in the western area with that in the eastern area (Fig. 1*b*) shows that the change in disequilibrium is not as coherent as it seems for oxygen. However, most of the $\delta^{13}C$ values are closer to equilibrium in the eastern core than in the western cores—a reverse trend to the oxygen trend.

Interspecific and intraspecific ranges

In the Holocene samples, interspecific Δδ ranges are near 1‰ or less for oxygen and more than 1‰ for carbon (Table 2, Fig. 1). Intraspecific (within species) ranges in both $\delta^{18}O$ and $\delta^{13}C$ are commonly of the order of several tenths of 1‰ (also see ref. 10). Maximum intraspecific ranges within single samples are near 1.5‰ for both $\delta^{18}O$ and $\delta^{13}C$. Isolated determinations should, therefore, be interpreted with caution as indicators of changes in either ambient conditions or vital effects.

From Fig. 1, the relative position of *O. umbonatus* data with respect to the general trend of the other three species suggests that *O. umbonatus* may be less affected by fertility changes, although more data are necessary to confirm this. Nevertheless, our data do not support the conclusion of Belanger *et al.*[31] that *P. wuellerstorfi* is a more reliable indicator of bottom water than *O. umbonatus*.

Oxygen isotope record of the past 15,000 yr

The relationships between the isotopic signals of various deep-sea benthic foraminifera are further illustrated by a 15,000-yr record, based on closely spaced samples of Box Core ERDC-123 (Fig. 2). The carbon-14 stratigraphy of this core[32] (see Fig. 2, lower scale) shows that sedimentation was continuous. The sedimentation rate is ~3 cm kyr^{-1} from the base of the core to ~20 cm, and changes rather abruptly to 1.8 cm kyr^{-1} above 20 cm in the core, at ~10,000 yr BP. Sharply lower sedimentation rates for the post-Glacial, compared with the Glacial, have been reported for this area[23,33].

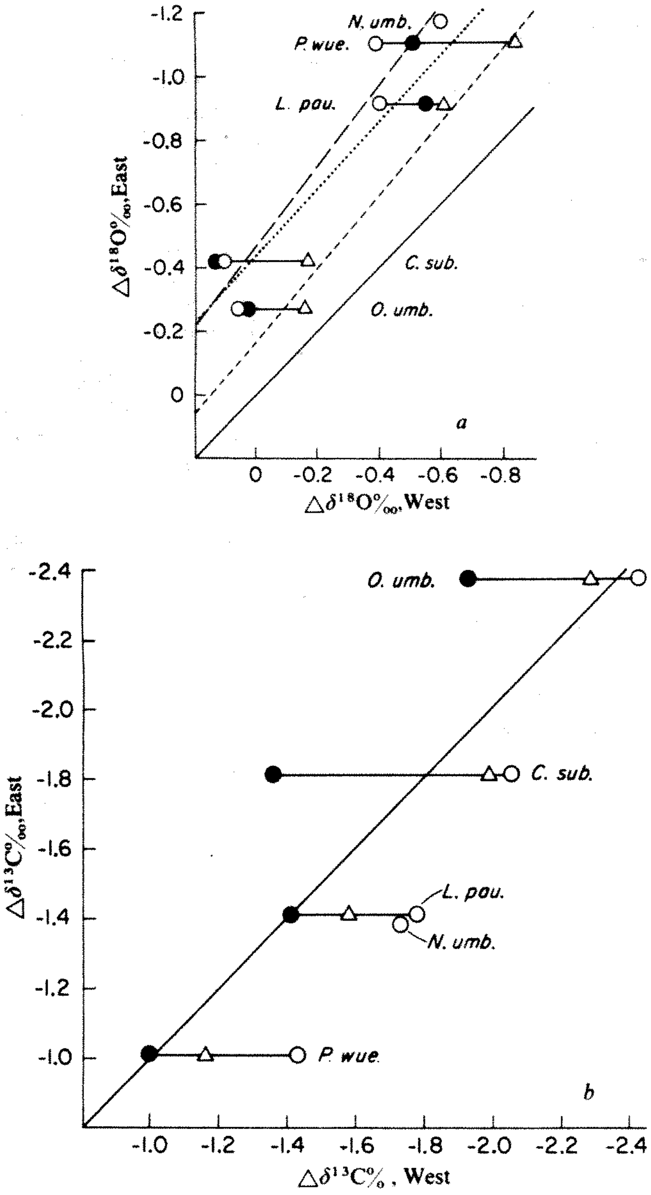

Fig. 1 Comparison of the degree of disequilibrium in recent benthic foraminifera for oxygen (*a*) and carbon (*b*) between west and east in the equatorial Pacific. $\Delta\delta$ values are from Table 2. Western cores: ERDC-92 (●), ERDC-123 (△), ERDC-135 (○); eastern core: PLDS-66. *N. umb.*, *Nuttalides umbonifera*; *P. wue.*, *Planulina wuellerstorfi*; *L. pau.*, *Laticarinina pauperata*; *C. sub.*, *Cassidulina subglobosa*; *O. umb.*, *Oridorsalis umbonatus*. The solid 45° line corresponds to an equal disequilibrium between west and east. The other lines are the best calculated fits for the oxygen isotopic data (long dashed line: ERDC-135, correlation coefficient of the fit, $r = 0.96$; dotted line: ERDC-92, $r = 0.93$; short dashed line: ERDC-123, $r = 0.99$).

The oxygen isotope record of shallow-living (*Globigerinoides sacculifer*) and deep-dwelling (*P. obliquiloculata* and *N. dutertrei*) planktonic foraminifera shows the familiar change from Glacial to post-Glacial values for this area[25]. The maximum rate of change occurs between 21 and 29 cm (13,000–10,000 ^{14}C yr). Three factors are involved in producing the change: (1) introduction of meltwater into the world ocean; (2) possible incomplete mixing of this meltwater; and (3) global warming. The relative importance of these factors to the rate of change is not clear, but we assume that the first can account for a total change of near 1‰, the second for a transient change of near 0.5‰, the third for about 0.4‰[24,34,35]. An additional factor, mixing by benthic organisms, decreases the recorded rate of change[36–39].

The oxygen isotope stratigraphy of benthic foraminifera also shows the deglaciation change, but continuing beyond 21 cm until values reach a light δ^{18}O plateau around 15 cm (7,500 ^{14}C yr BP). The difference in the isotope records does not necessarily indicate a 'lead-lag' relationship such as has been postulated for various Pleistocene palaeoceanographic signals[40,41]. The fact that the abundance of the carrier particles for the isotope signals changes across the Glacial–Holocene boundary will by itself change the shape of the signal, as pointed out earlier[34]. As the relative abundance of the benthic carrier decreases markedly across the boundary, its isotopic signal may lag behind that of the planktonic through the effects of mixing because proportionally more benthic signal carriers (with high δ^{18}O values) are mixed upwards when compared with the planktonic signal carriers. Recent numerical experiments by W. H. Hutson (personal communication) have demonstrated the importance of mixing on such lead-lag phenomena.

The various benthic signals are reasonably parallel, only the one of *F. favus* crosses any of the others. The rapid increase in δ^{18}O values in all four species near 10 cm (5,000 ^{14}C yr BP) and the distinct trend to lighter values near the surface of the sediment are remarkable. (The uppermost sediment in this core is in fact ^{14}C young and not yet absorbed into the mixed layer[32].)

The range of the deglacial δ^{18}O change, including the early Holocene plateau, is greatest in *P. wuellerstorfi*, the most oxygen-disequilibrated species of the four. Its range is 2‰. The other species show ranges between 0.9 and 1.4‰, for an average of 1.2‰. The cause of the benthic oxygen isotope plateau between 5,500 and 8,500 ^{14}C yr BP is not immediately clear, but it is possibly associated with the period of the "Climatic Optimum"[42].

We suggest the following interpretation of the oxygen isotope record: (1) a lag in the effect of glacial melting on the bottom water composition, with bottom waters reaching Holocene values ~2,000 yr after the upper waters; (2) a period in which benthic foraminifera have abnormally low ^{18}O values because of a decrease in bottom water production, and hence warming of bottom waters, during the climatic optimum; and (3) an increase of bottom water production after the climatic optimum, with a concomitant rapid drop in abyssal temperatures with the onset of "Neoglaciation"[42]. Future work will show whether these suggestions are acceptable or not. Clearly, however, ice volume cannot be read directly from the benthic signals (as has been variously proposed), because of: (1) differences in amplitudes between species; (2) existence of transient events throughout deglaciation and the Holocene; (3) mixing effects; and (4) intraspecific variation in δ^{18}O.

Carbon isotope record of the past 15,000 yr

The carbon isotope stratigraphy of the deep-dwelling planktonic foraminifera *P. obliquiloculata* is remarkable for its lack of structure. Apparently we need not postulate significant variation in δ^{13}C of upper ocean waters during the period in question.

The surface-dwelling *Globigerinoides sacculifer* shows a stepped signal: low values (1.65‰±0.15) from 15,000 to 9,000 ^{14}C yr ago, high values (2.0‰±0.2) since 9,000 yr BP. The change correlates with the previously mentioned changes in sedimentation rate and in benthic foraminiferal number. A distinct decrease in equatorial upwelling within the early Holocene, with concomitant stabilization of a ^{13}C-rich surface layer is suggested. A marked decrease in fertility from Glacial to post-Glacial time is also indicated by the δ^{13}C values of the fine sand fraction ('Fines'). Low δ^{13}C in this fraction is believed to indicate high metabolic activity[26], and such activity seems to decrease with time.

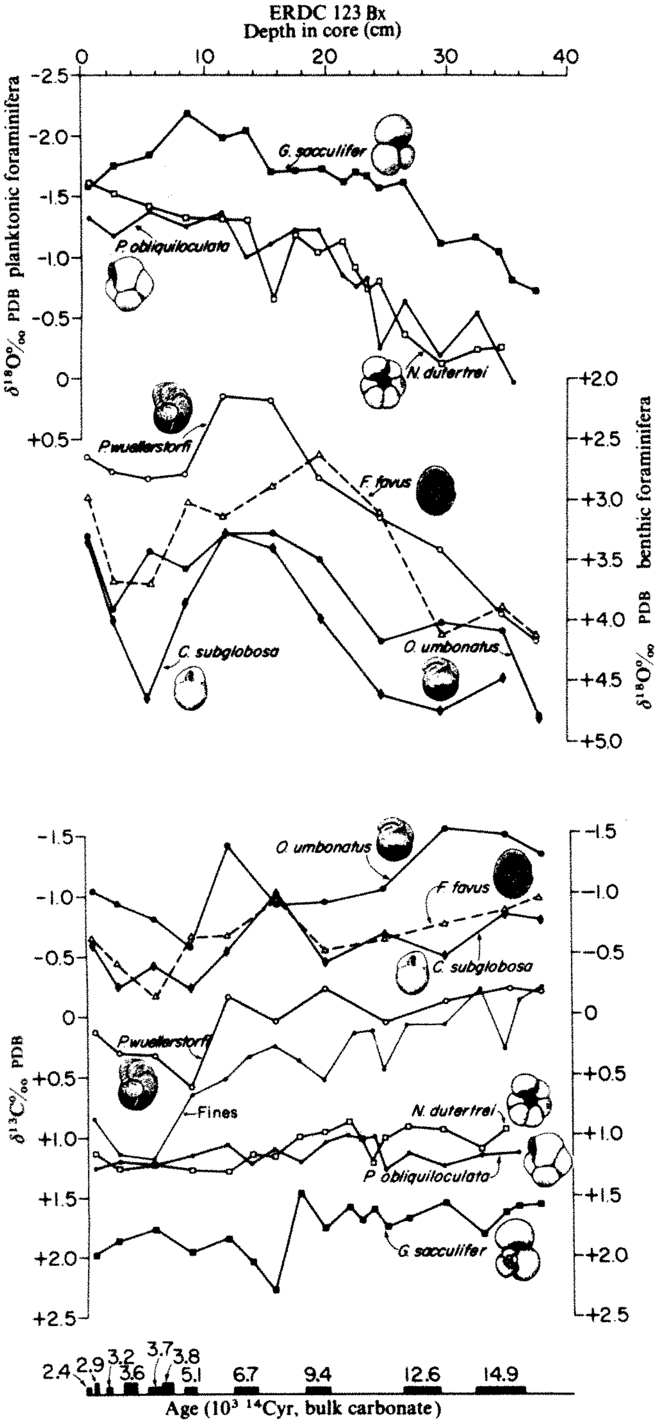

Fig. 2 Oxygen and carbon isotope stratigraphies in Box Core ERDC-123 for the shallow-living planktonic foraminifera *Globigerinoides sacculifer* (250–420 μm), the deep-dwelling ones *Pulleniatina obliquiloculata* and *Neogloboquadrina dutertrei* (250–420 μm) and the benthic species *Cassidulina subglobosa, Favocassidulina favus, Oridorsalis umbonatus* and *Planulina wuellestorfi* (>250 μm). Carbon isotope stratigraphy for the fine sand fraction ('Fines': 63–125 μm). Foram shells drawn by F. L. Parker (planktonics) and W. T. Coulbourn (benthics).

The decrease in fertility from Glacial to post-Glacial time is also reflected in an increase in δ^{13}C values of benthic foraminifera in post-Glacial sediments. Possibly the oxygen isotope plateau in the early Holocene is accompanied by a lightening of the ambient δ^{13}C values: if the plateau was partly due to warming, and hence incomplete mixing, isotopically light CO_2 should have built up. A CO_2 buildup would obscure a general δ^{13}C increase from lowered fertility, and shift the high benthic δ^{13}C values into the late Holocene. There is some indication in all four benthic signals that such a shift is indeed present, compared with the planktonic signal. Again, the effects of mixing on the signal, through changing signal carrier abundance may bias results in this direction.

Five of the benthic taxa analysed in this study (*C. subglobosa, F. favus, O. umbonatus, P. wuellerstorfi* and *Uvigerina* spp.) maintain the same relative positions in terms of δ^{18}O and δ^{13}C in Upper Miocene sediments[43], demonstrating that the relative intensity of vital effects in the various species tend to be retained over millions of years.

Conclusion

We have established the degree of disequilibrium precipitation in various deep-sea benthic foraminifera, and shown how this helps the interpretation of isotope record. Stratigraphies using multiple species are necessary for a more than superficial understanding of palaeoceanographic history, especially on a time scale of <10,000 yr. On this time scale, unfortunately, mixing processes disrupt the deep-sea record sufficiently to make stratiagraphic interpretations rather tentative, until more cores are studied and mixing processes are more quantitatively understood.

We thank Susan K. Culp, Richard F. Johnson, and Frances L. Parker for helpful discussions, and Thomas J. Walsh for assistance in collecting and sampling the box cores. We also thank Samuel M. Savin for constructive criticism. This study was supported by the NSF (Oceanography Section) grant OCE78-25587.

Mouse liver and salivary gland α-amylase mRNAs differ only in 5′ non-translated sequences

Otto Hagenbüchle, Mario Tosi, Ueli Schibler, Raymonde Bovey, Peter K. Wellauer & Richard A. Young*

Swiss Institute for Experimental Cancer Research, Chemin des Boveresses, 1066 Epalinges, Switzerland

The sequence of the 1,773-nucleotide major and 1,806-nucleotide minor mouse liver α-amylase mRNAs differ only with respect to approximately 30 additional residues at the extreme 5′ terminus of the minor species. Comparison of the liver α-amylase mRNAs with their salivary gland counterpart reveals that these mRNAs share identical coding and 3′-noncoding sequences, but contain distinct 5′-terminal residues. These data suggest that all three mRNAs might be transcribed from the same gene.

TO gain insight into the mechanisms which govern tissue-specific gene expression, we have investigated α-amylase mRNA biosynthesis in various mouse tissues. Early reports from other investigators indicated that α-amylase is produced in the pancreas, the salivary gland and the liver[1-3] and that the pancreatic protein differs from the other two with respect to antigenic and charge properties[4-9]. In our recent report of the primary structure of the α-amylase mRNAs which accumulate in the pancreas and the salivary gland, we found that the two mRNAs differ in nucleotide sequence, indicating that they are transcribed from different genes[10,11].

The liver α-amylase mRNA is less well characterized. Schibler *et al.*[10] showed that this mRNA is 100-fold less abundant and ~100 nucleotides longer than its salivary gland counterpart. However, the two species were found to have very similar sequences as indicated by their melting behaviour and resistance to S_1 nuclease digestion when part of α-amylase cDNA–mRNA hybrids. Restriction endonuclease digestion of cloned cDNAs made against liver and salivary gland α-amylase mRNA revealed no differences in cleavage sites for the various enzymes tested[12].

To elucidate structural relationships between α-amylase mRNAs produced in the salivary gland and liver in more detail, we have determined the nucleotide sequence of liver α-amylase mRNA. Here we report the intriguing finding that the liver and salivary gland α-amylase mRNAs encode identical proteins but differ in the terminal portion of their 5′-non-translated regions.

5′-terminal sequences account for the length difference between salivary gland and liver α-amylase mRNAs

Hybrids between salivary gland α-amylase cDNA and liver mRNA are resistant to S_1 nuclease along the entire length of the 1,600-nucleotide cDNA[10], suggesting that sequences which are responsible for the length difference between salivary gland and liver mRNAs reside at one or both ends of the liver species. To locate these extra sequences, we exploited the ability of RNase H to digest the RNA moiety of RNA–DNA hybrids[13-15]. The experimental approach is outlined in Fig. 1*a*. The 520-base pair *Eco*RI fragment of the cDNA clone pMSa104 (Fig. 1*b*), which contains translated sequences from the salivary gland α-amylase mRNA, was hybridized to polyadenylated RNA from pancreas, salivary gland or liver. Hybrids were then digested with RNase H and the products separated on a methyl mercury hydroxide agarose gel and transferred to diazotized (DMB) paper. The 5′ or 3′ RNase H-resistant RNA fragments were visualized by hybridization with appropriate 5′- or 3′-specific probes generated from the pMSa104 cDNA clone (Fig. 1*b*).

The autoradiographs shown in Fig. 1 indicate that sequences which account for the differences in size between the liver and salivary gland α-amylase mRNAs reside at the 5′ terminus. The results for the pancreas and salivary gland mRNAs (Fig. 1*c*) concur with those expected: only one major α-amylase mRNA accumulates in each of these two tissues and the salivary gland mRNA contains 80 more 5′-terminal noncoding residues than its pancreatic counterpart[10,11]. Two 5′-terminal liver RNA fragments are revealed in this experiment. Using the predicted sizes of the pancreas and salivary gland 5′-terminal fragments, we estimate that the two liver fragments are 490 and 520 nucleotides long. Densitometer tracings indicate that the larger fragment is present at 20% the level of the smaller one. For convenience, we will refer to these two liver RNAs as 5′-major and 5′-minor RNAs, reflecting their relative concentrations.

No apparent length differences are observed in 3′-terminal α-amylase mRNA fragments from the three tissues (Fig. 1*d*). However, an overexposure of the autoradiograph revealed a minor RNA fragment in both salivary gland and liver; Fig. 1*e* shows a longer exposure of the lane containing liver RNA. The size and abundance of this fragment indicate that it originates from a previously described minor α-amylase mRNA species (3′-minor RNA). Present at about 5% the level of total α-amylase mRNA in both tissues, the 3′-minor species contains major species sequences plus 237 additional nucleotides at its 3′ end[12].

Sequence analysis of liver α-amylase mRNAs

To determine the liver α-amylase mRNA sequence, our strategy included elucidating the cDNA sequence. Double-stranded cDNA was synthesized against liver poly(A)$^+$ RNA and cloned in *E. coli*[12]. Due to the low abundance of α-amylase mRNA in this tissue (0.02% of poly(A)$^+$ RNA), only one recombinant plasmid (pMLa52) was obtained. Restriction endonuclease mapping of pMLa52 DNA suggested that it contained sequences complementary to the 3′-minor α-amylase mRNA; subsequent sequence analysis of residues representing the extreme 3′ terminus confirmed this interpretation[12]. Because the 3′-minor species is simply an extended version of the 3′-major liver α-amylase mRNA (see above), we could use pMLa52 DNA to determine sequences for both mRNAs. Therefore, the entire sequence of the cDNA of pMLa52 was determined according to Maxam and Gilbert[16] as outlined in Fig. 2 legend. Nucleotides 518–1,773 of the liver α-amylase mRNA (Fig. 3) were elucidated from pMLa52. These residues are identical to those determined for the salivary gland α-amylase mRNA[11]. As 3′-minor nucleotide sequences have been reported elsewhere[12], only those for the 3′-major species are included in Fig. 3.

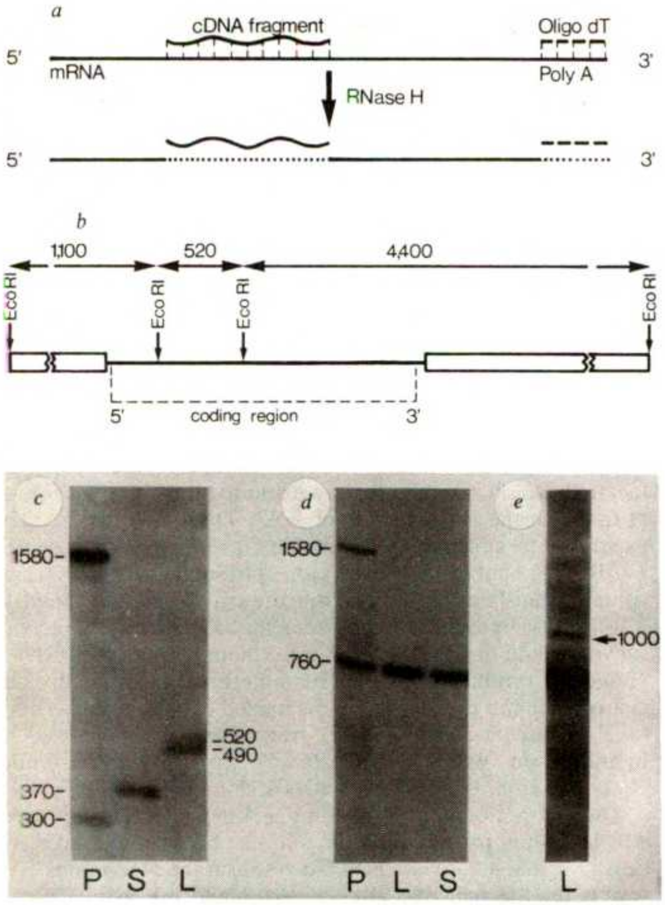

Fig. 1 Locating sequences which account for the length differences between liver, salivary gland and pancreas α-amylase mRNAs. *a*, the strategy used to generate 5′- and 3′-terminal fragments of α-amylase mRNA using RNase H. *b*, Diagram of pMSa104 DNA[10] linearized with respect to the pBR322 *Eco*RI site. Salivary gland α-amylase cDNA insert is represented as a line, pBR322 vector is boxed. Arrows delineate the *Eco*RI fragments used in this experiment. Numbers are in base pairs. *c*, *d*, Autoradiographs of DBM paper-bound RNase H-resistant RNA fragments probed with 5′-end-specific (1.1 kilobase *Eco*RI fragment from pMSa104; *c*) or 3′-end-specific (4.4 kilobase *Eco*RI fragment from pMSa104; *d*) labelled DNA restriction fragments (see *b*). Poly(A)$^+$ RNA from pancreas (P, 500 ng), salivary gland (S, 1 μg) and liver (L, 40 μg) was hybridized to 100 ng (300 ng for pancreas) of the 520-base pair *Eco*RI restriction fragment from pMSa104 (*b*) in a final volume of 100 μl of 80% formamide, 0.05% SDS, 0.4 M NaCl, 1 mM EDTA, 10 mM PIPES, *p*H 6.4, for 3 h at 45 °C. After ethanol precipitation, the mRNA/DNA hybrids were digested with RNase H for 15 min at 37 °C in 10 mM Tris-HCl *p*H 7.6, 0.13 M NH_4Cl, 0.01 M Mg acetate, 5% (w/v) sucrose, 20 $\mu g\ ml^{-1}$ oligo(dT), and 1 unit RNase H (Enzo) in a final volume of 30 μl (8 units RNase H in 300 μl for liver). After phenol extracting and ethanol precipitating, equivalent amounts of RNase H-resistant α-amylase mRNA sequences were electrophoresed on a 2% methyl mercury hydroxide agarose gel, transferred to DBM paper[10,20] and hybridized with the 5′- or 3′-end-specific probes. Numbers are in nucleotides, the 1,580-nucleotide bands in lane P represent uncleaved, deadenylated α-amylase mRNA. *e*, A 20-fold longer exposure of lane L in *d*. An arrow indicates the minor species fragment.

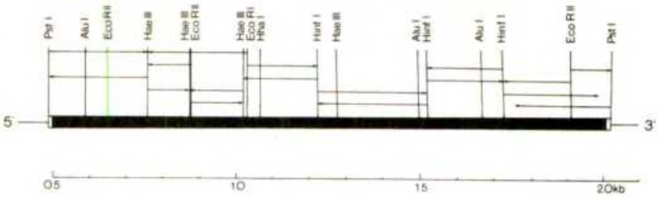

Fig. 2 Restriction map and strategy used to determine the nucleotide sequence of the liver α-amylase cDNA insert of recombinant plasmid pMLa52. Restriction endonuclease cleavage sites were determined by the technique of Smith and Birnstiel[21]. 5′-end-labelled fragments were sequenced according to Maxam and Gilbert[16]. The direction and extent of sequence information determined for each fragment examined are indicated by an arrow. The black box represents mRNA sequences, the open boxes indicate poly(dG-dC) generated during the cloning procedure. kb, kilobases.

To obtain primary structure information for 5′-terminal sequences not included in the cDNA clone, we used reverse transcriptase-catalysed primer extension as described by Hagenbüchle *et al.*[11]. A 50-nucleotide single-stranded DNA fragment, isolated from the salivary gland α-amylase cDNA clone pMSa104 and containing nucleotide residues 191–241 (Fig. 3), was 5′-end-labelled according to Maxam and Gilbert[16] and hybridized to liver polyadenylated RNA. Two cDNA transcripts were produced after incubation with AMV reverse transcriptase which differed by approximately 30 nucleotides. The sizes and relative amounts of the two cDNAs were consistent with those predicted by the RNase H sizing experiment for the two liver mRNAs (Fig. 1). A unique sequence was elucidated for the 5′-major species cDNA (residues 1–191, Fig. 3) and simultaneous determination of the cytosine and purine residues of the 5′-minor species cDNA revealed that it is an extended version of the 5′-major species (data not shown). Notably, nucleotides 159–191 (Fig. 3) are identical to those determined for the comparable portion of the salivary gland α-amylase mRNA. Due to the low cellular concentration of liver α-amylase mRNA, direct RNA sequencing by chemical decapping and 5′-end labelling was not feasible; therefore, the 5′-terminal few residues could not be determined.

Sequences determined for the liver α-amylase cDNA produced by primer extension (nucleotides 1–191, Fig. 3) do not overlap those elucidated from pMLa52 DNA (nucleotides 518–1,773, Fig. 3). Of these, residues 159–191 and 518–1,773 are identical to those determined for the salivary gland α-amylase mRNA. We assume that the two α-amylase mRNAs also share residues 192–517 (sequences not examined for the liver species) because S_1 nuclease digestion and thermal melting curves of liver α-amylase mRNA/salivary gland α-amylase cDNA hybrids reveal no sequence heterogeneity[10].

Features of the liver α-amylase mRNAs

The results obtained by a combination of RNase H digestion, primed cDNA synthesis and sequence analysis indicate that several α-amylase mRNA species accumulate in the liver (Fig. 4). The 1,773-nucleotide major mRNA (5′-major/3′-major) accounts for 80% of the total α-amylase mRNA population. The remaining 20% are composed of 5′-minor species which contain ~30 additional nucleotides at their extreme 5′ termini. Among these two mRNA species, 5% contain the 237 3′-minor species residues; the distribution of 3′-minor species among 5′-major and 5′-minor mRNAs has not been determined. We do not know whether these minor species serve some special function or whether they represent products of alternative synthesis or processing pathways.

Fig. 3 Comparison of the nucleotide sequence of the major liver α-amylase mRNA and its salivary gland counterpart. Numbering begins with nucleotide X (which represents the few initial nucleotides that were not determined, see text) in the liver mRNA. The nucleotide residues 112–158 shown for the salivary gland mRNA were taken from O.H. *et al.*[11] but contain two nucleotides (residues 113 and 114) that were excluded from the sequence reported earlier. The two mRNAs are assumed to be capped. S and L indicate the tissue-specific salivary gland and 5′-major liver α-amylase mRNA leaders. The first AUG codon is underlined; that actually used to initiate α-amylase synthesis is boxed, as is the terminator triplet. Both mRNAs predict the amino acid sequence shown below the nucleotide sequence.

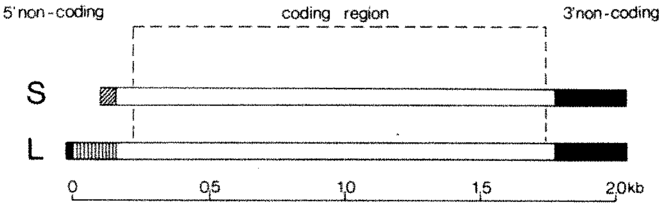

Fig. 4 Schematic comparison of the liver and salivary gland α-amylase mRNAs. The diagram is based on data presented here and elsewhere[11,12], as described in the text. The open boxes represent common sequences; the black boxes designate residues found in the minor salivary (S) and liver (L) α-amylase mRNA species. Tissue-specific leader residues are shaded diagonally for salivary gland mRNA or vertically for the liver mRNA species. Numbering is that in Fig. 3.

Tissue-specific 5'-noncoding segments

Figure 3 compares the salivary gland α-amylase mRNA sequence with that of its major liver counterpart. The two mRNAs share nucleotides 159–1,773, which include the entire coding and 3'-noncoding regions. These salivary gland mRNA sequences have been discussed in detail previously[11]. Briefly, translation of the α-amylase precursor can occur from only one coding frame (the two others contain many termination triplets); this frame predicts a precursor protein whose characteristics mirror those determined for α-amylase produced *in vivo* and *in vitro*[10,17].

In addition to the coding and 3'-noncoding regions, a portion of the 5'-non-translated region is identical in the liver and salivary gland α-amylase mRNAs. The 204- and 93-nucleotide 5'-terminal noncoding regions share the 48 residues immediately adjacent the coding region. This common segment (nucleotides 159–206, Fig. 3) has the intriguing feature that it begins with an AUG codon which is not used to initiate translation of α-amylase even though it is the one nearest the 5' terminus. The first AUG is followed by a lysine codon, then the termination triplet UAA. The AUG used to initiate translation[11] lies 14 codons downstream. As all other eukaryotic cellular mRNAs for which complete sequence information is available initiate translation at the AUG codon located nearest the 5' end[18], the salivary gland and liver α-amylase mRNAs are apparent exceptions. Whether the first AUG in these α-amylase mRNAs has some regulatory role in translation is unclear.

It is the initial 158 nucleotides of the major liver species and the 47 5'-terminal residues of its salivary gland counterpart that distinguish the α-amylase mRNAs which accumulate in these two tissues. Hence, these two species have distinct 5'-terminal noncoding regions but direct the translation of an identical α-amylase polypeptide. The presence of distinguishing 5'-non-translated sequences might be the consequence of tissue-specific requirements for the rate of translation initiation. Although the influence of particular sequences 5' to the AUG initiation codon is unclear[18], translation initiation efficiency *in vitro* can be affected by the length of the 5'-non-translated region (C. Queen, personal communication). Therefore, the different lengths of the 5'-non-translated segments in salivary gland and liver α-amylase mRNAs (93 and 204 residues, respectively) might influence their relative translatability. Finally, the distinct 5'-non-translated segments might also specify different lifetimes for these tissue-specific mRNAs.

The observation that liver and salivary gland α-amylase mRNAs share identical coding and 3'-noncoding residues suggests that they are transcribed from the same DNA sequence. Indeed, recent analysis of genomic DNA demonstrates that both liver and salivary gland α-amylase mRNAs are specified by a single DNA sequence in the mouse haploid genome[19]. Two different segments of DNA specify the distinct 5'-non-translated regions of these mRNAs. These findings have implications for the mechanisms which govern the expression of this α-amylase gene; for example, tissue-specific splice events must be responsible for the correct biosynthesis of α-amylase mRNA in the liver and salivary gland.

Control of vascular permeability by polymorphonuclear leukocytes in inflammation

Caroline V. Wedmore & T. J. Williams*

Department of Pharmacology, Institute of Basic Medical Sciences, Royal College of Surgeons of England, Lincoln's Inn Fields,
London WC2A 3PN, UK

Polymorphonuclear leukocytes infiltrate tissues in response to an inflammatory stimulus to remove invading micro-organisms and cell debris. We present evidence that these scavenging cells have another, more sophisticated role in that they are involved in the control of fluid efflux through the blood vessel wall which leads to tissue oedema.

SINCE the first observations of leukocytes accumulating at a site of inflammation, their relationship to changes occurring in blood vessels has been a source of controversy. Studies of animal models of inflammation (for example, rat paw oedema in response to carrageenin[1]) have suggested that acute vascular responses, vasodilatation and increased vascular permeability, result from the sequential release of low molecular weight mediators—histamine, serotonin, bradykinin and prostaglandins[2]. During these acute vascular changes polymorphonuclear (PMN) leukocytes, predominantly neutrophils, accumulate slowly in the tissues reaching significant numbers after several hours. Based on these models, and allergic models such as the Arthus reaction[3], several mechanisms have been proposed whereby PMN leukocytes could contribute to oedema. The most widely accepted of these, first postulated by Metchnikoff[4], was that during phagocytosis PMN leukocytes release substances (lysosomal enzymes[5] for example) which damage vascular endothelial cells—the cells lining the blood vessel wall which are normally responsible for retaining plasma proteins within the lumen. We suggest an alternative hypothesis, that PMN leukocytes, responding to a chemical signal in the tissue, can control the permeability of the blood vessel wall to plasma proteins. Three such signalling substances are described here. Although PMN leukocytes are present in high numbers in tissues several hours after the initiation of an inflammatory response, the evidence suggests that these cells interact with vascular endothelial cells to regulate permeability within a few minutes of the inflammatory stimulus.

---

* To whom correspondence should be addressed.

The chemical mediators of inflammatory oedema in man are unknown; there is little evidence that histamine, serotonin and bradykinin are important. We suggest that the mechanisms involving leukocytes described here may be more relevant.

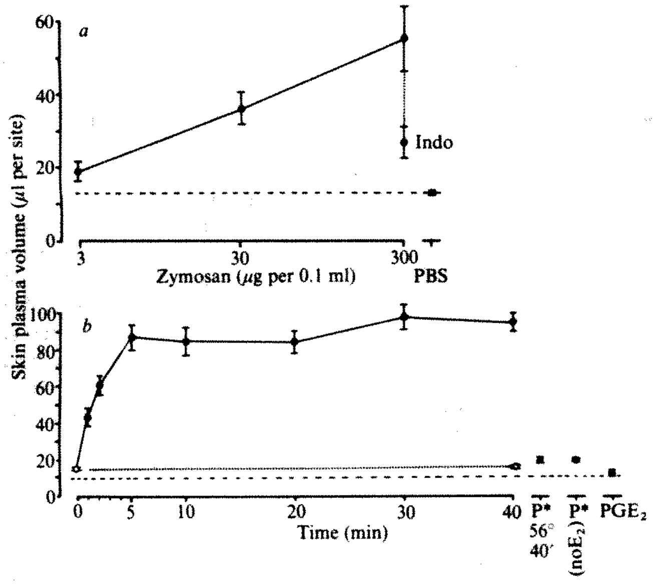

Fig. 1 *a*, Dose–response curve of oedema induced in rabbit skin by intradermal injection of zymosan. *b*, Time course of generation of permeability-increasing activity in blood plasma incubated with zymosan at 37°C. In all experiments plasma exudation was measured using the accumulation of intravenously injected ^{131}I-human serum albumin in rabbit (male NZW, 3–3.5 kg) dorsal skin in response to 0.1-ml intradermal injections of the agents. After a fixed period (30 min in all experiments except where stated) animals were killed, the skin was removed, the injection sites were excised (16-mm diameter punch) and counted in a γ-counter. *a* Shows the increase in exudate volume (measured over a 90-min period) in response to increasing amounts of injected zymosan. Indomethacin (Indo), an inhibitor of prostaglandin synthesis, injected locally at 0 min and 60 min (3×10^{-9} mol per site) suppressed exudation, as shown, an effect which was reversed by exogenous prostaglandin[14]. Oedema induced by intradermally injected zymosan was also suppressed by nitrogen mustard (1.75 mg per kg intravenous injection, 4 days before testing in the skin) which depletes circulating PMN leukocytes. Plasma volumes (90 min accumulation) of skin sites injected with 100 μg of zymosan were 40.0±6.3 μl in control animals, and 13.1±2.1 μl in depleted animals ($n=4$ rabbits, saline control (PBS, phosphate-buffered saline) values 16.6±1.8 μl and 15.7±2.0 μl, respectively). Unlike suppression of oedema produced by indomethacin, the effect of nitrogen mustard was not reversed by exogenous prostaglandin. In *b*, following incubation of plasma with zymosan for periods up to 40 min, zymosan was removed by centrifugation and the plasma was mixed with PGE_2 (3×10^{-10} mol per site) before injection into the skin. Exudation was measured over a 30-min period. Permeability-increasing activity was rapidly generated in plasma during incubation (response $t_{1/2}=100$ s) but oedema was only demonstrable when PGE_2 was present. Little exudation was induced by the following: plasma incubated alone, tested with PGE_2 (open symbols); plasma incubated with zymosan for 40 min but tested without PGE_2 (P* no E_2); or PGE_2 alone. Preheating plasma to 56 °C for 40 min (P* 56°40′) before the addition of zymosan prevented the generation of activity (40 min incubation with zymosan and the plasma tested with PGE_2). All the results are shown as the mean ±s.e.m. for six replicate injections. Values for PBS controls are shown as dashed lines (as in all the figures).

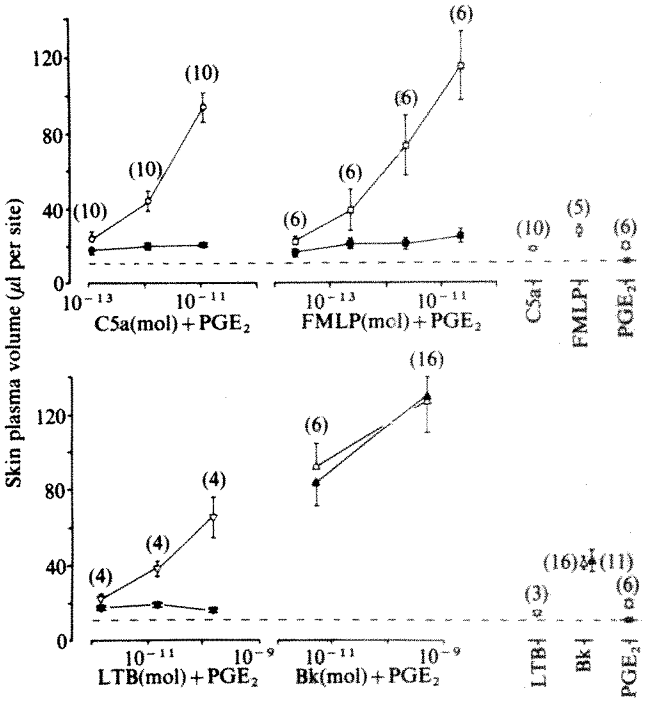

Fig. 2 Oedema induced in rabbit skin by rabbit C5a, FMLP, leukotriene B_4 (LTB) and bradykinin (Bk); the potentiating effect of PGE_2; and the inhibitory effect of leukocyte depletion. All responses were measured over a 30-min period. Numbers in parentheses refer to the number of animals used in each test; the mean response to six replicate injections of each substance was determined for each animal. Open symbols show responses in untreated animals. Closed symbols show responses in animals treated 4 days previously with a single intravenous injection of nitrogen mustard (1.75 mg per kg). The symbols on the right-hand side show responses to C5a, FMLP, leukotriene B_4 and bradykinin at the highest doses used in the experiments. PGE_2 was used at a dose of 3×10^{-10} mol per site throughout. In normal rabbits (PMN leukocyte count $3.5\pm1.1\times10^6$ per ml blood, $n=6$ rabbits) very small responses were elicited by C5a, FMLP, leukotriene B_4 and PGE_2 when tested alone (20–30 μl responses to LTB_4 alone at higher doses have been reported[30]). However, when mixed with PGE_2 the leukotactic substances were very potent in inducing oedema. Bradykinin produced distinct responses alone and these were enhanced by PGE_2. In PMN leukocyte-depleted rabbits (PMN leukocyte count $4.0\pm1.4\times10^4$ per ml blood, $n=6$ rabbits), although responses to bradykinin and bradykinin+PGE_2 were unaffected, responses to the leukotactic substances in combination with PGE_2 were virtually abolished. Responses to histamine+PGE_2, like those to bradykinin+PGE_2, were unaffected by PMN-leukocyte depletion—histamine (2.3×10^{-8} mol per site)+PGE_2 (3×10^{-10} mol per site) produced a response of 82.7±2.8 μl in controls and 78.0±14.5 μl in treated animals ($n=4$ rabbits).

Prostaglandins and oedema formation

The presence of microorganisms in a tissue stimulates leakage of plasma from small blood vessels resulting in tissue oedema. We investigated the mechanisms underlying this vascular response by injecting yeast cell walls (zymosan) into rabbit dorsal skin and measuring plasma leakage using the local accumulation of intravenously injected ^{131}I-albumin[6]. Zymosan induces acute oedema with a peak rate of plasma exudation at 1–3 h, decreasing to low levels by 4–5 h (ref. 7). Figure 1*a* shows that the volume of oedema fluid accumulating is regulated according to the stimulus size (the quantity of zymosan injected).

We deduced that zymosan stimulates the release in the skin of two chemicals which exert a synergistic action to mediate oedema ('the two mediator hypothesis'[8]). The first mediator increases vascular permeability by an action involving vascular endothelial cells; the second greatly potentiates plasma exudation by inducing relaxation of arteriolar smooth muscle cells and thus increasing the blood supply to the tissue. The vasodilator mediator is thought to be a prostaglandin[7–10] (PGE_2 or PGI_2)[9] produced by cell membranes; little exudation is induced when prostaglandin synthesis is inhibited (for example, by indomethacin[11]) as shown in Fig. 1*a*.

Involvement of the complement system

We next investigated the identity of the endogenous permeability-increasing mediator. We obtained evidence[12-14] that this mediator is derived from the complement system—the enzyme system in blood plasma and tissue fluid which is responsible for lysis of microorganisms. As shown in Fig. 1*b*, incubation of blood plasma with zymosan at 37°C resulted in the rapid generation of a substance which could increase vascular permeability when injected into skin. This substance induced little oedema unless mixed with a vasodilator prostaglandin. The active substance has been purified and identified[14] as a polypeptide fragment of the fifth component of complement, C5a. The activity is stable in plasma and is therefore probably due to C5a devoid of the carboxyl-terminal arginine (C5a des Arg); the arginine group, which is necessary for histamine-releasing (anaphylatoxic) activity in other species, is cleaved by plasma carboxypeptidase B (ref. 15). We have shown that oedema induced by synergism between rabbit C5a and prostaglandin is not dependent on histamine release[12,14].

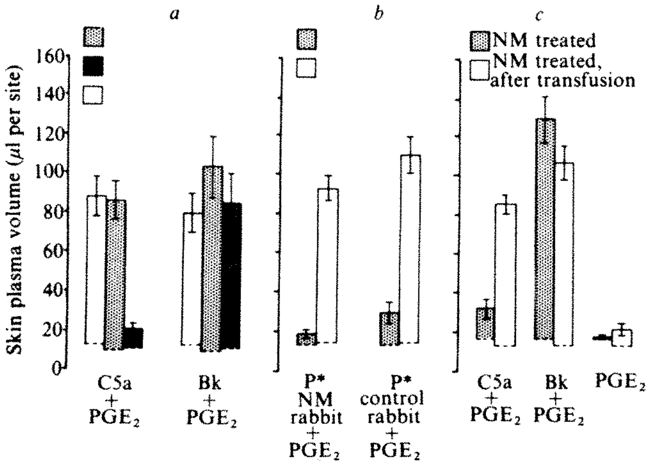

Fig. 3 *a*, Results of an experiment designed to show that nitrogen mustard suppresses responses in skin by an action on dividing bone marrow cells, rather than by an action on the skin itself. Rabbits were set up in three groups of four individuals. The first group were untreated (open columns). The second group were injected, via an ear vein, with nitrogen mustard (1.75 mg per kg) while a clamp was applied to the terminal descending aorta (stippled columns) and the clamp was removed after 10 min. As nitrogen mustard has a very short half life in the circulation, this procedure allowed access of nitrogen mustard to the dorsal skin but not to the bone marrow of the hind limbs. The third group were sham-operated and injected with nitrogen mustard via an ear vein (hatched columns). As in the second group a volume of blood (17% of total blood volume, measured by isotope dilution) was not exposed to nitrogen mustard; this volume of blood was withdrawn from the individuals of the sham-operated group before drug injection, maintained at 37 °C and reinjected after 10 min. Four days later, agents were injected into the skin and responses measured over a 30-min period. All three groups responded to bradykinin (5×10^{-10} mol per site) + PGE_2 (3×10^{-10} mol per site). Animals whose skin had been exposed to nitrogen mustard but whose bone marrow had been protected (group 2) responded normally to C5a (1.5×10^{-11} mol per site) + PGE_2 (3×10^{-10} mol per site) showing that inhibition of responses by nitrogen mustard was not due to an effect of the drug on the skin. *b*, Results of an experiment designed to investigate the effect of nitrogen mustard (NM) on C5a generation in plasma. Rabbits were set up in two groups of five individuals, one group injected with nitrogen mustard (stippled), the other untreated (open columns). Four days later plasma from each animal was incubated with zymosan (1 mg ml^{-1}, 37 °C for 30 min). The zymosan was then removed by centrifugation. Plasma was mixed with PGE_2 (3×10^{-10} mol per site) and responses measured in the skin (30 min period) of the donor animal and in an animal in the other group. Treated animals did not respond to plasma from either group; however, untreated animals responded to plasma from both groups. These results demonstrate that nitrogen mustard pretreatment suppresses responses to C5a, but not its production. *c*, Results of an experiment to show skin responses in a depleted animal before, and after, cross blood transfusion with a normal animal. Six such experiments were carried out; three depleted animals showed only a small elevation in circulating PMN leukocytes following transfusion and these animals did not respond to C5a + PGE_2. In three other experiments the circulating PMN leukocyte count was elevated following transfusion and these recipient animals responded to C5a + PGE_2. ^{125}I-albumin was injected intravenously into both normal and depleted animals. C5a (1.5×10^{-11} mol per site) + PGE_2 (3×10^{-10} mol per site) and bradykinin (5×10^{-10} mol per site) + PGE_2 (3×10^{-10} mol per site) were then injected intradermally into the depleted animal. After 30 min, blood was transfused (6 ml min^{-1}) by a peristaltic pump interposed between carotid artery cannulae and ear vein cannulae. After a further 60 min, pumping was stopped, the treated animal was injected intravenously with ^{131}I-albumin, and the skin was again tested with the same combinations of agents. Following transfusion the circulating PMN leukocyte count was elevated from 3×10^4 ml^{-1} to 2.4×10^6 ml^{-1}; only a small change was seen in the mononuclear leukocyte count, from 2.3×10^6 to 3.2×10^6 ml^{-1}. The animal clearly responded to C5a + PGE_2 following transfusion. Results shown as mean ± s.e.m. for six replicate injections. Hatched bars, nitrogen mustard-treated; open bars, nitrogen mustard-treated after transfusion.

Central role for the PMN leukocyte

In both intact and des Arg forms, C5a shows powerful chemoattraction for PMN leukocytes *in vitro*[16]. Thus, is the permeability-increasing activity of C5a in the skin dependent on the presence of PMN leukocytes *in vivo*? Zymosan failed to induce oedema in the skin of rabbits depleted of circulating PMN leukocytes using nitrogen mustard (results in Fig. 1 legend), providing the first indication that the action of C5a might be leukocyte dependent.

To investigate this further, the activity of histamine and bradykinin (both with established permeability-increasing activity) was compared with that of three leukotactic substances[16-18] in the skin of normal animals and animals depleted of circulating PMN leukocytes. The leukotactic substances used were: rabbit C5a (ref. 14), a polypeptide of approximately 70 amino acids; leukotriene B_4, a dihydroxy fatty acid formed from arachidonic acid by the action of leukocyte lipoxygenase[19]; and *N*-formyl-methionyl-leucyl-phenylalanine (FMLP), a synthetic substance based on formyl peptides secreted by bacteria in culture[18]. Figure 2 shows that in normal animals leukotactic substances alone induced little oedema, but, mixed with PGE_2, all three were highly potent permeability-increasing substances. However, in animals given intravenous nitrogen mustard 4 days before testing, to deplete circulating PMN leukocytes[20,21], the leukotactic substances were ineffective, even when combined with PGE_2. In normal animals both bradykinin and histamine induced some oedema when injected alone into the skin and the responses were greatly enhanced by PGE_2. However, these responses were unaffected by nitrogen mustard pretreatment. These results suggested that bradykinin and histamine increase vascular permeability by acting directly on vascular endothelial cells ('direct-action mediators'), but that C5a, leukotriene B_4 and FMLP can only act in the presence of PMN leukocytes ('polymorph-dependent mediators').

Nitrogen mustard (administered as a single intravenous injection) is short-lived in the blood and depletes circulating PMN leukocytes by preventing replication of stem cells in bone marrow. However, as the skin itself is exposed to the drug, a direct effect on the skin could not be excluded. A clamp applied to the terminal descending aorta during, and for 10 min after, an ear-vein injection of nitrogen mustard provided access for the drug to the skin, but not to the bone marrow of the hind limbs. As Fig. 3*a* shows, 4 days later animals treated in this way responded normally to C5a + PGE_2. Thus, suppression of responses by nitrogen mustard was not due to an effect on the skin. Furthermore, 4 days after nitrogen mustard treatment, the numbers of circulating mononuclear cells and platelets were little affected[20] and, as shown in Fig. 3*b*, the plasma of animals pretreated with nitrogen mustard could be activated normally to produce permeability-increasing activity, that is, C5a (complement levels measured by haemolytic assay are also known to be unaffected[20]).

All these results suggested that PMN leukocytes are essential for the permeability response to the leukotactic substances. Nevertheless, we could not raise circulating cell numbers sufficiently to restore responsiveness in previously depleted animals by intravenous or intra-arterial injections of PMN leukocytes. This probably indicates the importance of the surface properties of the cells which may change following removal from the body. Experiments using whole blood were more successful: in three out of six experiments it was possible to elevate circulating levels of PMN leukocytes in depleted rabbits by whole-blood cross-transfusion (6 ml min^{-1} for 60 min) using normal donor rabbits. Figure 3*c* shows that responsiveness to C5a was restored in these rabbits.

In all experiments Evans blue dye was mixed with ^{131}I-albumin to indicate plasma leakage sites in the skin. Responses to different agents were visually similar; however, direct-action mediators could be clearly distinguished from polymorph-dependent mediators by their time courses of action using radioisotope techniques, as shown in Fig. 4. Oedema was first detectable at 1.5 min after injection of bradykinin + PGE_2 but at 6 min with C5a + PGE_2 (surprisingly early considering the necessity for PMN leukocytes). A more striking difference was that responses to bradykinin and histamine were of very short duration, as expected from earlier experiments[22] (for example, bradykinin $t_{1/2} = 4$ min), whereas those to leukotactic substances were protracted (for example, C5a $t_{1/2} = 95$ min).

From our results we conclude that mechanisms exist which regulate local fluid accumulation in response to the presence of microorganisms in tissue. This process, although remarkably fast in onset, seems to be dependent on PMN leukocytes. PMN leukocytes are attracted to the site and their function is controlled by chemicals released in the tissue. The chemical signals can be generated in response to microorganisms in tissue fluid (for example, C5a), can be derived from microorganisms themselves (for example, FMLP), or, perhaps in later phases of the response, derived from leukocytes (for example, leukotriene B_4). These substances induce little oedema alone; the concomitant generation of vasodilator prostaglandin seems to be essential for oedema formation.

How do PMN leukocytes increase vascular permeability?

The manner in which PMN leukocytes increase vessel wall permeability remains undetermined. PMN leukocytes, during their passage through the vessel wall, may secrete enzymes which break down substances present at junctions between adjacent endothelial cells, or the enzymes may act on basement membrane underlying endothelial cells. Alternatively, PMN leukocytes may secrete a substance which affects endothelial cells, perhaps causing contraction. If PMN leukocytes do secrete such a substance, phagocytosis does not seem to be essential because soluble factors (C5a, FMLP and leukotriene B_4) or particulate matter (zymosan) can induce increased vascular permeability equally well.

Secretion by PMN leukocytes may be unnecessary as electron micrographs of tissues removed shortly after injection of C5a showed PMN leukocytes between the endothelial cell layer and basement membrane, many underneath endothelial cell junctions. Direct contact of that sort may be required for endothelial cells to respond. If PMN leukocytes located under junctions were to swell (as has been observed in response to C5a *in vitro*[23]) this could open the junctions.

PMN leukocytes in other types of inflammatory reaction?

We believe that these mechanisms have developed as an essential part of the host defence system to control the supply of complement from the blood to an infected tissue in order to regulate local killing of microorganisms. Similar mechanisms probably operate in allergic inflammation to regulate the supply of complement, antibodies and other plasma components to the tissue. In many models of inflammation oedema is known to be suppressed by prostaglandin synthesis inhibitors, complement depletion and PMN leukocyte depletion; these observations are consistent with our hypothesis.

Pulmonary oedema in man is often associated with a local accumulation of PMN leukocytes, for example in adult respiratory distress syndrome due to septicaemia, during haemodialysis and cardiopulmonary bypass[24]. There is evidence that the interaction of C5a with PMN leukocytes is important in these conditions[24,25].

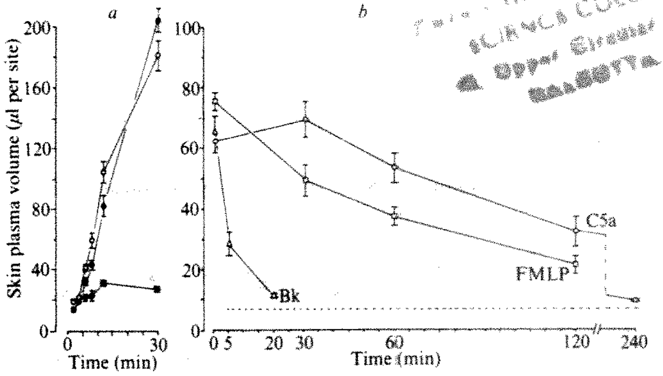

Fig. 4 The onset time of the vascular permeability increase induced by injection of C5a (*a*), and the duration of increased permeability induced by C5a and FMLP (*b*). *a*, Rabbits were injected intravenously with ^{131}I-albumin and killed 30 min later. Intradermal injections were given at intervals (shown in the abscissa) before death. The injections given were: ○, C5a (1.5×10^{-11} mol per site) + PGE_2 (3×10^{-10} mol per site); ●, C5a + PGE_2 + mepyramine maleate (3.5×10^{-9} mol per site); and ◆, PGE_2 alone. Six minutes after injection, responses to C5a + PGE_2 were significantly greater than control values produced by PGE_2 alone ($P < 0.01$, Student's unpaired *t*-test). Mepyramine, at doses which abolished matching responses to histamine + PGE_2, had a limited suppressor effect on responses; responses to C5a + PGE_2 + mepyramine were also significantly elevated above controls at 6 min ($P < 0.01$). Bradykinin and histamine responses were earlier in onset, for example bradykinin (5×10^{-10} mol per site) + PGE_2 (3×10^{-10} mol per site) onset time 1.5 min ($P < 0.01$). In the experiments shown in *b*, bradykinin (5×10^{-10} mol per site), C5a (1.5×10^{-11} mol per site) and FMLP (2.3×10^{-11} mol per site) were injected at intervals (as shown in abscissa) before a local superimposed injection of PGE_2 (3×10^{-10} mol per site). Labelled albumin was injected intravenously immediately before the PGE_2 injection and responses measured over a period of 30 min. (This procedure is designed to negate the effect of PGE_2 metabolism on the result.) Clearly the durations of action of the leukotactic substances were quite different from that of bradykinin: bradykinin $t_{1/2} = 4$ min, C5a $t_{1/2} = 95$ min, and FMLP $t_{1/2} = 50$ min. Histamine responses were similar in duration to those of bradykinin (results not shown). Results are represented as mean ± s.e.m., $n = 4$ replicates in *a*, and $n = 6$ replicates in *b*.

In chronic, self-destructive inflammation (such as rheumatoid arthritis), mononuclear cells are intimately involved with the underlying pathogenesis, and these cells could interact with the vessel wall in the manner we have described. In such chronic conditions, PMN leukocytes may be important because phases of active oedema formation are associated with the appearance of high numbers of these cells in the tissues[26]. Our simple model may be relevant to these complex events as rheumatoid fluid has been shown to contain prostaglandins[27], leukotriene B_4 (ref. 28) and C5a (ref. 29).

In summary, we suggest that PMN leukocytes and endothelial cells lining the blood vessel wall cooperate to regulate the supply of macromolecules to a tissue, and that this may represent a fundamental component of the inflammatory response.

We thank our colleagues in the Department of Pharmacology, Royal College of Surgeons, for discussions. C5a, from zymosan-activated rabbit plasma, was purified and characterized in collaboration with Dr P. J. Jose[14]. We thank Dr A. W. Ford-

Hutchinson and his colleagues for the gift of leukotriene B_4, and M. J. Peck and M. J. Forrest for technical assistance. This work was supported by the MRC.

Nucleotide and corresponding amino acid sequences encoded by α and β tubulin mRNAs

P. Valenzuela, M. Quiroga, J. Zaldivar, W. J. Rutter, M. W. Kirschner & D. W. Cleveland

Department of Biochemistry and Biophysics, School of Medicine, University of California, San Francisco, California 94143

Most of the mRNA sequences coding for α and β tubulin in embryonic chick brain have been determined by sequencing of cloned cDNA copies of these mRNAs. From a 1,682-base pair cDNA sequence we have deduced the entire protein sequence for β tubulin. For α tubulin, all but about 38 N-terminal amino acids have been deduced from the cDNA sequence. Although tyrosine has previously been shown to be post-translationally added to the C-terminus of α tubulin by a specific ligase, we conclude that the primary post-translational event must be the removal, not the addition, of tyrosine because a terminal tyrosine is encoded by the mRNA.

TUBULIN is the principle subunit of microtubules, an intracellular cylindrical filamentous structure present in almost all eukaryotic cells. Microtubules function as structural and motile elements in mitosis, intracellular transport, flagellar movement and the cytoskeleton (for review see refs 1, 2). The microtubule, 24 nm in diameter, is comprised of 13 protofilaments each containing an alternating array of α and β tubulin subunits spaced every 4 nm. In the soluble form it is generally assumed that tubulin is a heterodimer composed of one α and one β chain each of molecular weight (MW) about 55,000.

The structure of the microtubule is highly conserved and at the resolution obtained by electron microscopy (~2 nm) no differences in structure have been observed between microtubules from *Tetrahymena*, sea urchin and mammalian sources. The tubulin subunit will form copolymers across wide species lines and the conditions for assembly of tubulin are similar for each species. Recently, we have shown that cDNA clones for chicken embryonic α and β tubulin (which do not cross-hybridize to each other) will hybridize in stringent conditions to genomic DNA from sea urchin and *Drosophila*, as well as mammals[3,4], and in less stringent conditions to yeast, *Chlamydomonas* and trypanosomes (N. Neff, D. Botstein, D. Cleveland and N. Agabian, unpublished results).

This high degree of conservation is not surprising in view of the large number of conserved structural interactions of tubulin. The tubulin dimer has two GTP binding sites, one exchangeable and the other not, a single colchicine binding site, two binding sites for vinblastine, and other drug binding sites. In addition, the tubulin structure must be constrained by the requirement for interaction with other tubulin molecules in the microtubule lattice as well as with microtubule-associated proteins.

Despite considerable recent interest in the biochemistry of tubulin, there are important gaps in our knowledge of its primary structure and genetic complexity. Evidence suggesting some homology and possible common evolutionary origin of the α and β peptides relies on the published N-terminal 25 amino acids in α and β tubulin[5]. Additional other known data are the sequence of some unordered peptides[6] and the 78 C-terminal amino acids of the α chain[7]. A true appreciation of the degree of homology between α and β chains, however, awaits more complete sequence information. Additional sequencing studies are also crucial to understanding the microheterogeneity, post-translational modification and structure of the tubulin proteins themselves.

Recently, we have constructed cDNA clones from embryonic mRNA of chicken brain and have isolated clones containing α or β tubulin sequences. We report here the complete DNA sequence of the cDNA from these clones. The β tubulin clone

0028–0836/81/080650—06$01.00

contains the entire coding sequence for the protein and extensive 5′ and 3′ untranslated regions of the mRNA. The α clone contains >90% of the coding sequences and some of the 3′ untranslated region of the α tubulin mRNA.

DNA sequences of plasmids pT2 and pT1

The construction of bacterial plasmids containing sequences homologous to α or β tubulin mRNAs from embryonic chick brain has been described elsewhere[3]. We initially demonstrated by mRNA hybridization followed by *in vitro* translation of specifically bound mRNA that the hybrid plasmids pT2 and pT1 carry β and α tubulin sequences, respectively. The sequencing strategies for both pT1 and pT2 are presented in Fig. 1. All sequencing was done by the method of Maxam and Gilbert[8]. In all cases both strands of the cDNAs were sequenced unless a particular single-strand sequence was exceptionally clear.

The sequence of the 1,681 nucleotides of the cDNA from pT2, the β tubulin plasmid, is given in Fig. 2*a*, along with the corresponding protein sequence which it predicts. The direction and frame of reading were established by comparison with the published N-terminal 25-amino acid sequence for chick brain β tubulin[5] and by the presence of the 3′ poly(A) tract at one end of the cDNA. In addition, the C-terminus of the protein was established by the appearance of three in-phase stop codons and by the presence of a C-terminal peptide with a composition (15 out of 25 residues acidic) similar to that reported for α tubulin[7]. Plasmid pT2 thus contains the complete coding sequence for the 445 amino acids of β tubulin as well as 87 nucleotides 5′ to the methionine initiation codon and 226 nucleotides between the UGA stop codon and the site of polyadenylation. The predicted MW of β tubulin is 49,935 and the sequence deduced agrees with 19 of the 25 N-terminal residues reported by Luduena and Woodward[5] for chick brain β tubulin. The cDNA sequence predicts that residues 11 and 15 are glutamic acid, whereas glutamine was the amino acid residue previously reported[5] at these positions. Similarly, we predict that residues 10, 13 and 17 are glycine whereas threonine was originally reported at these positions.

The sequence of the chick brain α tubulin clone, pT1, is given in Fig. 2*b*. The direction and frame of reading were established by identification of the known C-terminal protein sequences for porcine brain α tubulin. Although pT1 contains 123 nucleotides 3′ to the UGA stop codon, no poly(A) tract is present; therefore some regions of the 3′ untranslated region of the mRNA may be missing. Furthermore, pT1 does not contain the complete 5′

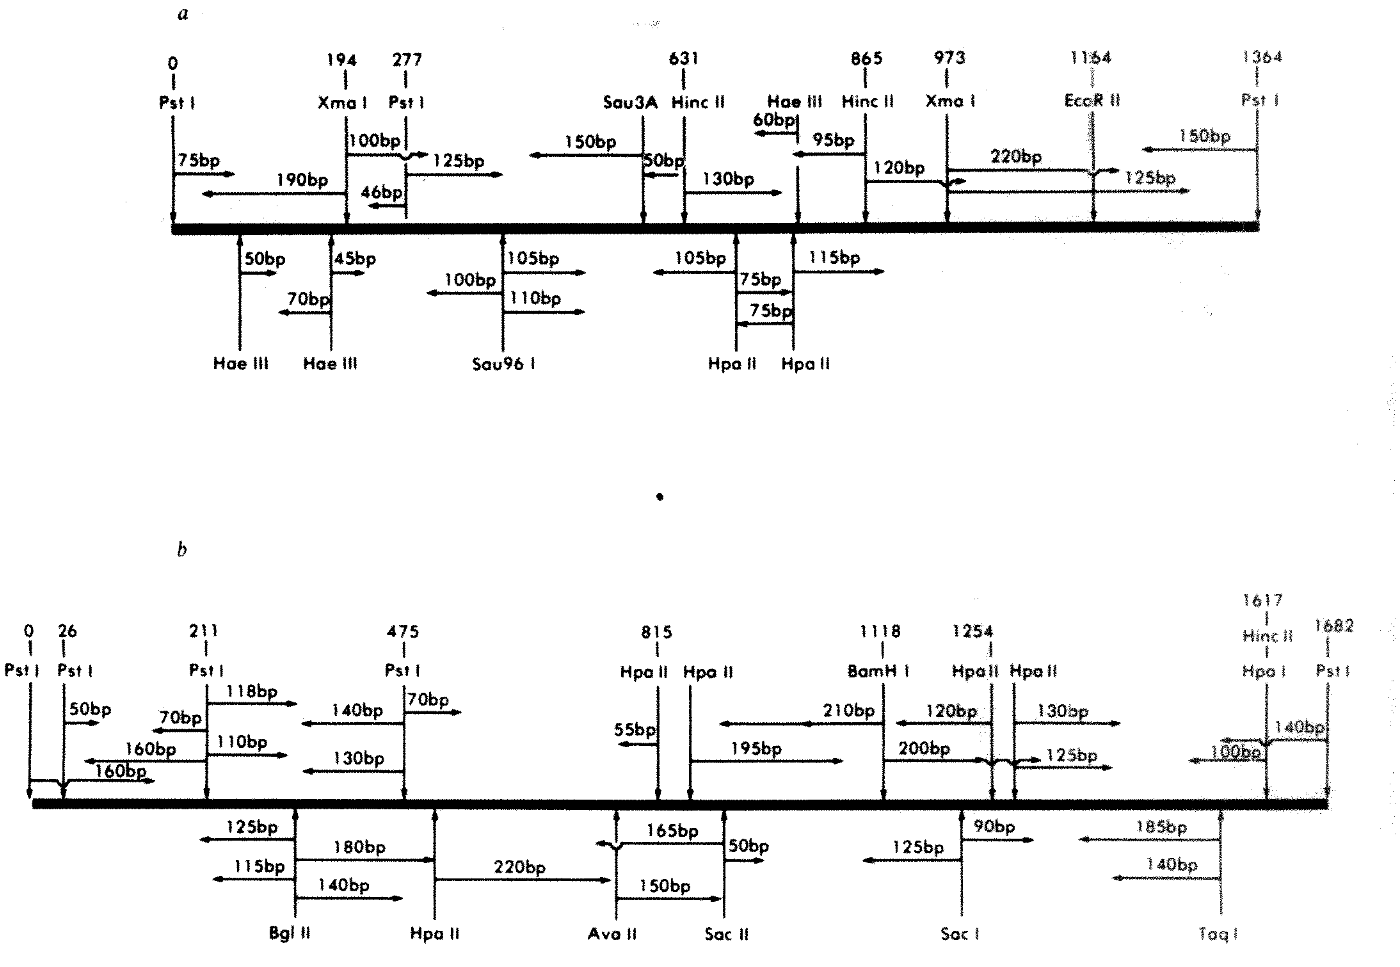

Fig. 1 Sequencing strategy for the chicken brain α and β tubulin cDNAs. *a*, α tubulin cDNA; *b*, β tubulin cDNA. Nucleotide residues are numbered in the direction from 5′ to 3′ in the message strand. The extent and direction of each fragment sequenced is shown by the horizontal arrows. Only the restriction sites used as starting points are shown. For end labelling, DNA was treated with 5 μg of bacterial alkaline phosphatase (Worthington) at 37 °C for 60 min in 20 mM Tris-HCl, *p*H 8.0, phenol-extracted and treated with 10 units of T4 polynucleotide kinase (Boehringer) at 37 °C for 30 min in a reaction mixture containing 50 mM glycine, *p*H 9.5, 10 mM $MgCl_2$, 10 mM dithiothreitol, 0.1 mM spermidine and 0.001 mM [γ-^{32}P]ATP (~3,500 Ci $mmol^{-1}$). Fragments labelled at only one end were isolated by gel electrophoresis after either digestion with a restriction enzyme or strand separation. DNA sequencing was carried out by the method of Maxam and Gilbert[8].

Fig. 2 *a*, The nucleotide sequence of chicken brain *β* tubulin mRNA, determined from the double-stranded cDNA insert of pT2 (ref. 3). The predicted complete amino acid sequence is shown above the RNA sequence. *b*, The partial nucleotide sequence of chicken brain *α* tubulin mRNA, determined from the double-stranded cDNA insert of pT1 (ref. 3). The predicted partial amino acid sequence of *α* tubulin is also indicated. The amino acids have been numbered by comparison with the complete sequence of *β* tubulin mRNA shown in *a*.

sequences of the mRNA. By alignment with the deduced β tubulin protein sequence from above, we predict that pT1 lacks the sequences coding for amino acids 1–38 of α tubulin. We used this assumption tentatively to number the amino acids for the α chain in Fig. 2*b*. The predicted MW for α tubulin is ~50,040. The predicted sequence corresponds to the existing protein sequence data in the following respects: (1) with the exception of the terminal tyrosine residue (see below), the C-terminal 78 amino acids reported for porcine brain α tubulin are identical to the chick sequence reported here, and (2) the sequences of four (α4D, α4HB, α4I and α4CA) of the eight unordered cyanogen bromide fragments reported for beef brain α tubulin[6] are identical to peptides in the chick sequence. One of the remaining reported peptides, α4J, contains a single substitution at position 302 in our sequence, and one peptide (α4HA) is actually a β tubulin peptide (residues 148–164).

Fig. 4 Codon usage in α and β tubulin mRNAs. The numbers indicate the frequency with which individual codons are used in the coding regions of the mRNAs. OC, OP and AM designate the terminator codons ochre, opal and amber, respectively. *a*, α tubulin mRNA; *b*, β tubulin mRNA.

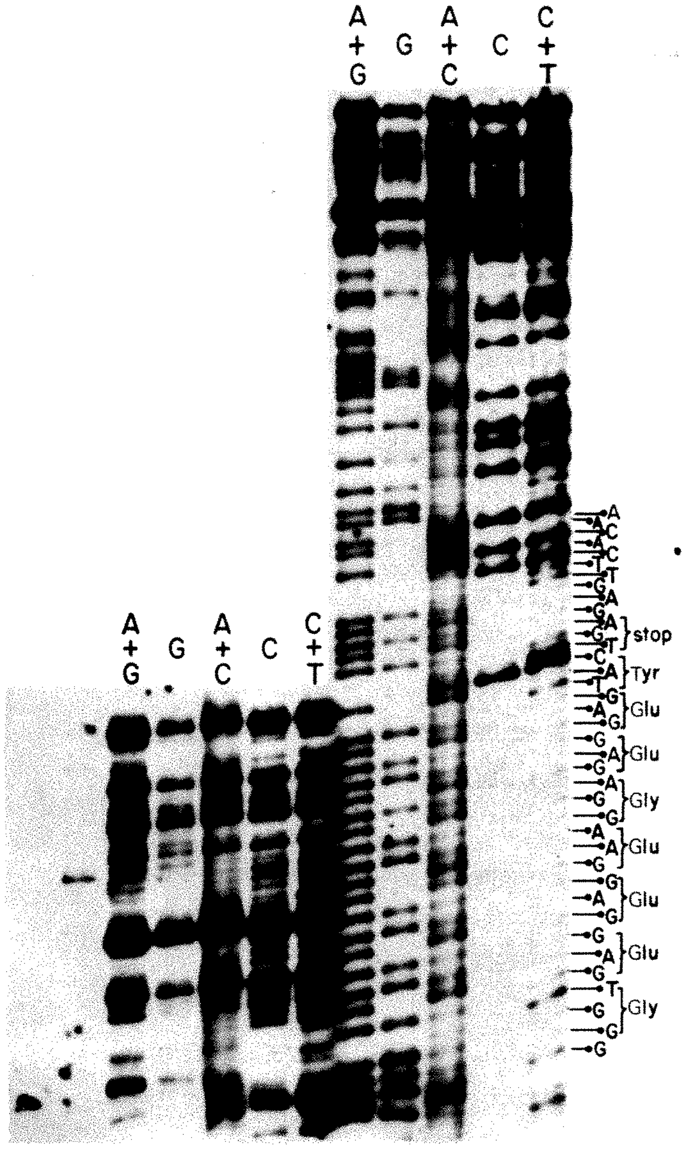

Fig. 3 Autoradiogram of a sequencing gel showing the region coding for the C-terminus of α tubulin. Note that the last codon before the UGA stop codon is UAC, which codes for tyrosine.

The tubulin subunits have been widely seen to migrate on SDS or SDS-urea polyacrylamide gels with mobilities characteristic of proteins of MW ~55,000–56,000 for α tubulin and 53,000–55,000 for β tubulin (for example, see ref. 9). Comparable mobilities have been found for the *in vitro* translation products of α and β tubulin from mRNA translated in reticulocyte or wheat-germ systems (for example, see ref. 10). Surprisingly, we have unambiguously determined that the polypeptide encoded by one β tubulin mRNA has a MW of 49,935. Similarly, although we cannot be completely certain of the size of the α tubulin chain, by homology with the β tubulin sequence and by comparison with unpublished protein sequence data of porcine brain α tubulin (H. Ponstingl and collaborators, unpublished results), we predict that the MW of the α tubulin chain is slightly greater than 50,000. Because the mobilities of *in vitro* synthesized chains are indistinguishable from those of the mature polypeptides, post-translational modification cannot account for the differences in estimated and actual molecular weights.

Note also that the β chain contains 19 methionines and the α chain probably contains 11 methionines (using the data of Luduena and Woodward[5] for amino acids 1–25 coupled with the sequence of cyanogen bromide fragment α4CB of Lu and Elzinga[6], which seems to be derived from amino acids 22–36 of the α chain of beef α tubulin). In agreement with previous results[5], this predicts a ratio in methionine contents of 1.7:1, that is, the expected ratio of incorporation of label into each chain if each are translated at comparable rates or in comparable amounts. This could be a useful number for investigators using methionine-labelled materials.

The C-terminal residue of *α* tubulin is tyrosine

An enzyme has recently been reported which is capable of post-translationally adding a tyrosine residue to the C-terminal end of *α* tubulin[11-14]. The enzyme is specific for *α* tubulin, requires ATP and functions in the presence of protein synthesis inhibitors. Purified *α* tubulin has been reported to contain between 15 and 50% tyrosine on the C-terminal end[7,8,15]. Historically, then, C-terminal tyrosylation has been viewed as a post-translational modification of the *α* chain. However, it is now clear from the nucleotide sequence that *α* tubulin mRNA contains a coded terminal tyrosine (Fig. 2*b*). The sequencing gel demonstrating the tyrosine UAC codon immediately before the UGA stop codon is shown in Fig. 3. Although the functional significance of tyrosylation and detyrosylation remains unclear, these new data demonstrate that the primary post-translational

Fig. 5 Comparison of the amino acid sequences predicted from the *α* and *β* tubulin mRNAs. The predicted protein sequences for *α* and *β* tubulin have been aligned to show regions of homology. Open circles indicate homologous, conservative substitutions. Boxed regions indicate areas of high homology. For completeness, the sequence of the first 25 amino acids of chick brain *α* tubulin deduced by Luduena and Woodward[5] is also shown. *Identical amino acids in the two sequences.

event is not the addition but the removal of tyrosine from the C-terminus. This in turn strengthens the argument that there is probably a cyclic process of detyrosylation and tyrosylation and that this may be an important factor in modulating the activity of tubulin in the cell.

Codon usage in α and β tubulin

Figure 4*a*, *b* illustrates the prevalence of codons utilized for each of the amino acids in the translated frames of α and β tubulin, respectively. Surprisingly, strong biases are observed for both tubulins in the case of codons in which the third position is occupied by a G or C. For example, the threonine codons ACC and ACG are used 28 times in both α and β sequences, whereas the ACU and ACA codons are used only twice in either sequence. This contrasts with the reported codon usage for other chicken mRNAs sequenced to date. In ovalbumin mRNA[16], the ACU and ACA codons are used 11 times, but ACC is used only 4 times and ACG not at all. Similarly, for the *src* and *env* proteins of Rous sarcoma virus[17], the known threonine codon usages are 15:18 and 3:6 for ACC+ACG:ACA+ACU. Overall, codons which have G or C in the third position are utilized in the two tubulin sequences 9.6 times more frequently for α tubulin and 8.7 times for β tubulin than codons ending in A or U. The corresponding ratios for ovalbumin, *src* and *env* are 0.9, 2.5 and 1.0. The significance of the disparate codon usage is yet unclear; however, it may reflect some constraint on tubulin mRNA sequences beyond simple conservation of protein sequence.

Homologies between α and β tubulin

The amino acid sequences which we have deduced for α and β tubulin are shown in Fig. 5. The two sequences have been aligned to highlight regions of homology. The tubulins show several interesting features. First, the two sequences are 40–55% homologous throughout, depending on whether exact homology or conservative substitutions are considered. Such homology was first suggested by Luduena and Woodward[5] when they sequenced the N-termini of each chain and found that 11 out of 25 residues were identical. This homology, though distributed among all regions of the sequences, appears in more than 15 clusters of conserved amino acids. For example, the C-terminal regions of both chains contain highly acidic runs of homologous amino acids. Residues 387–411 (numbers are with respect to the β sequence) represent a cluster of 25 amino acids of which all but three are homologous and residues 429–443 comprise a cluster of 14 amino acids of which 11 are homologous. At the nucleic acid level we also find considerable sequence homology (~50%), again with some strongly conserved clusters of nucleic acid residues. An example of this DNA homology can be found in the nucleic acid sequences coding for the amino acids 58–70. Out of 13 amino acids, 11 are homologous in this region; 33 out of 39 nucleic acid residues are identical.

Overall, our sequencing data unambiguously demonstrate that substantial sequence homology exists at both the protein and nucleic acid sequence levels for α and β tubulin. These data confirm the widely held contention that the two tubulin subunits arose from a common ancestral sequence.

As a complementary approach to determining homology we have predicted secondary structure from the amino acid sequences by the methods of Garnier *et al.*[18] and Chou and Fasman[19] for α and β tubulin. With the exception of the C-terminal regions which are both predicted to be highly α helical, additional levels of structural homology were not obvious.

Further comments

The sequence data presented here demonstrate that α and β tubulin share substantial sequence homology and thus probably derived from a common ancestor. There has been speculation that sequence homology might exist between tubulin and muscle proteins. Krauhs *et al.*[20] have reported the location of such homology between actin and α tubulin at residues 22–31 of actin and some residues of α tubulin. This portion of the actin sequence, conserved in all actins sequenced so far[21–26], is ^{22}Ala-Gly-Asp-Asp-Ala-Pro-Arg-Ala-Val-Phe; the corresponding tubulin sequence which we have deduced is ^{57}Ala-Gly-Lys-His-Val-Pro-Arg-Ala-Val-Phe. Thus 7 out of 10 residues in the two proteins, including one stretch of five, are identical. Whether this reflects true homology due to a common binding site for nucleic acid cofactors or a common accessory protein, or whether the homology is merely coincidental remains to be determined by further evolutionary studies.

The hexanucleotide sequence, AAUAAA, has been found ~20 nucleotides from the poly(A) in almost all known polyadenylated RNA sequences and is thought to be the signal for such polyadenylation. However, we find the heptanucleotide, ACAUAAA, located 22 nucleotides 5′ to the beginning of the poly(A) in our β tubulin cDNA. In addition, other mRNAs, like those encoding rat pancreatic amylase[27] and anglerfish pancreatic somatostatin[28], have recently been shown to carry the variant, AAUUAAA. These variations probably reflect flexibility in the sequence requirement of this site.

Heterogeneity of both α and β tubulin chains has been reported many times. This heterogeneity has been observed repeatedly by one- or two-dimensional gel analyses and peptide mapping, and recently by genetic analysis[29,30]. Indeed, we have demonstrated that multiple gene sequences exist for α tubulin and for β tubulin in several organisms (that is, at least four α and four β genes in chicken and *Drosophila*—see refs 3, 4). The availability of the entire protein sequence for one α tubulin and one β tubulin from embryonic chick brain should facilitate additional efforts (1) to localize the regions of heterogeneity of different tubulin subunits and (2) to explore the functional significance of each heterogeneity.

We thank Sonia Bock, David Agard and Dr H. Martinez for their assistance with the computer programs used in the DNA and protein sequence analysis. This work was supported by NIH grants GM 25157 to P.V. and GM 26875 to M.K.

Can negative molecular ions be detected in dense interstellar clouds?

Eric Herbst

Department of Physics, Duke University, Durham,
North Carolina 27706

The recent laboratory measurement[1-3] of rapid radiative electron attachment processes

$$\mathrm{A + e \rightarrow A^{-}}h\nu$$

where A is a molecular species has renewed speculation on whether negative molecular ions can be synthesized efficiently in dense interstellar clouds. We argue here that for certain interstellar species A, the abundance ratio [A⁻]/[A] may be as high as 0.01–0.1 in commonly assumed physical conditions. If this abundance ratio were correct, negative molecular ions might be detectable in dense interstellar clouds if their microwave spectral frequencies had been determined in the laboratory. It will be shown, however, that this is currently an unlikely prospect.

In recent studies[4-6] of the gas phase chemistry of 'dense' interstellar clouds, the major processes considered in the ambient conditions of low density (10^4–10^6 cm^{-3}) and low temperature (10–50 K) are reactions between positive ions and molecules. These produce polyatomic ions and, on reaction with electrons, a variety of neutral molecules. Cosmic-ray penetration of the clouds produces both an initial assortment of positive ions and electrons. Although the subsequent formation of negative ions through radiative attachment of electrons has been considered[7], it has been concluded that negative ions are both scarce and only a minor contributor to ion–molecule synthetic processes. The scarcity results from the generally slow rate of radiative attachment.

Consider a molecular species A: in dense interstellar clouds, the negative ion $\mathrm{A^-}$ can be formed and depleted by the reaction sequence

$$\mathrm{A + e} \xrightarrow{k_{\mathrm{ratt}}} \mathrm{A^{-}} + h\nu \qquad (1)$$

$$\mathrm{A^{-} + B} \xrightarrow{k_2} \mathrm{AB + e,\ C^{-} + D} \qquad (2)$$

$$\mathrm{A^{-}} + h\nu \xrightarrow{k_3} \mathrm{A + e} \qquad (3)$$

$$\mathrm{A^{-} + I^{+}} \xrightarrow{k_4} \text{Products} \qquad (4)$$

where B and $\mathrm{I^+}$ represent generic neutral and positively-charged species, respectively. If $\mathrm{A^-}$ is at steady-state, the abundance ratio $[\mathrm{A^-}]/[\mathrm{A}]$ is

$$\frac{[\mathrm{A^{-}}]}{[\mathrm{A}]} = \frac{k_{\mathrm{ratt}} f_{\mathrm{e}}}{k_2 f_{\mathrm{B}} + k_3/n + k_4 f_{\mathrm{I^{+}}}} \qquad (5)$$

where n is the total gas density and f_{i} refers to the fractional abundance of species i. Typical values of k_2 are $\sim 10^{-9}$ cm^{-3} s^{-1} (ref. 8) (independent of temperature) and, of k_4, are $\sim 10^{-7}$–10^{-8} cm^3 s^{-1} at room temperature with $T^{-1/2}$ dependence[9]. The rate coefficient k_3 for photodetachment can generally be neglected in dense clouds for negative ions of several electron volts stability. High pressure, saturated three-body attachment rate coefficients have been studied extensively for stable neutral species[10] and found to vary widely—these values are useful upper limits to the radiative attachment coefficients. For most neutral species, high pressure attachment coefficients are considerably below collision rate coefficients ($\sim 10^{-7}$ cm^3 s^{-1}) at room temperature. High pressure attachment and measured autodetachment rates[10] can lead to an estimate for radiative attachment rate coefficients; such estimates show that for most neutral species these coefficients are quite small at room temperature. Therefore, the recent measurement of 'rapid' (~0.1–0.01 of the collision rate) room temperature radiative attachment coefficients at low pressure by the ICR technique is indeed intriguing[1,2]. There are no laboratory attachment and detachment data for most interstellar neutral species capable of forming negative ions, thus a theoretical treatment is required. A simple theory for k_{ratt} can be derived from phase space considerations[11-13]. Assuming that no vibrational excitation of the neutral species need be considered, the theory reduces to the following expression for k_{ratt}:

$$k_{\mathrm{ratt}}\,(\mathrm{cm^3\,s^{-1}}) \sim \frac{10^3 h^3 (kT)^{-1/2}}{(2\pi m_{\mathrm{e}})^{3/2}} \times \frac{g_{\mathrm{A^-}}}{2g_{\mathrm{A}}} N_{\mathrm{v}}(\mathrm{EA}) \qquad (6)$$

where the computed value of k_{ratt} cannot exceed the (unknown) rate coefficient for temporary electron capture. In equation (6) h is Planck's constant; m_{e}, the electron mass; $N_{\mathrm{v}}(\mathrm{EA})$, the vibrational density of states of $\mathrm{A^-}$ at an internal energy equal to the electron affinity; k, the Boltzmann constant; and g_{A} and $g_{\mathrm{A^-}}$, the electronic degeneracy factors of A and $\mathrm{A^-}$. Equation (6) is capable of reproducing the large experimental value[1,2] of $k_{\mathrm{ratt}} = 2\times10^{-8}$ cm^3 s^{-1} at 300 K for $\mathrm{SF_6}$ attachment if, as has been assumed[11], the vibrational frequencies of $\mathrm{SF_6^-}$ are half those of $\mathrm{SF_6}$. In general, the lack of known negative-ion vibrational frequencies limits the usefulness of equation (6) even if the statistical assumptions embodied in it are correct.

According to equation (6), k_{ratt} will be large when $N_{\mathrm{v}}(\mathrm{EA})$ is large. The vibrational density of states is a severe function of internal energy and molecular size[12,13] and increases greatly with both increasing electron affinity and molecular size. Based on equation (6) and a knowledge of interstellar chemistry, the most abundant interstellar molecular negative ions stem from neutral free radicals with estimated large (>2eV) electron affinities. For a variety of these species, such as $\mathrm{C_4H}$, $\mathrm{C_5N}$, $\mathrm{C_7N}$, $\mathrm{C_9N}$, $\mathrm{C_2H_2CN}$, $\mathrm{C_2H_3O}$, $\mathrm{C_2H_3O_2}$ and possibly $\mathrm{C_3N}$, equation (6) can be used to make plausible radiative attachment rate coefficients near the collision limit of 10^{-7} cm^3 s^{-1} at cloud temperatures of 10–50 K. The first and last radicals mentioned have been detected in clouds[14,15] while the others are possible on synthetic grounds[4-6]. The list has been prepared by removing hydrogen atoms from known stable interstellar molecules. Negative ions formed from such radicals are likely to react with atomic hydrogen via associative detachment processes, for example:

$$\mathrm{C_3N^{-} + H \longrightarrow IHC_3N + e}$$

Assuming that the fractional abundance of atomic hydrogen in dense clouds is $f_{\mathrm{B}} \sim 10^{-4}$ (refs 4–6), k_{ratt} is $\leqslant 10^{-7}$ cm^3 s^{-1}, k_4 is $\sim 10^{-6}$ cm^3 s^{-1}, k_2 is $\sim 10^{-9}$ cm^3 s^{1}, and $f_{\mathrm{I^+}} \simeq f_{\mathrm{e}}$, we obtain from equation (5) that

$$[\mathrm{A^{-}}]/[\mathrm{A}] \leqslant 10^6 f_{\mathrm{e}}/(1 + 10^7 f_{\mathrm{e}}) \qquad (7)$$

Estimates for f_{e} in dense clouds range from 10^{-7}–10^{-8} (refs 4–6, 16). For $f_{\mathrm{e}} \geqslant 10^{-7}$, equation (7) predicts $[\mathrm{A^-}]/[\mathrm{A}]$ to be $\leqslant 0.1$. For the more conservative value of $f_{\mathrm{e}} \sim 10^{-8}$, $[\mathrm{A^-}]/[\mathrm{A}] \leqslant 0.01$. Note that for equation (7) to apply, $[\mathrm{A^-}] < [\mathrm{e}]$.

The major uncertainty in our argument is whether or not radiative attachment rate coefficients near the collision-limited value of $\sim 10^{-7}$ cm^3 s^{-1} occur for only a few measured species[1,2] mostly larger than known interstellar molecules, or whether some smaller radicals with large electron affinities also possess such large values of k_{ratt}. The above simple theory supports the latter possibility. Still, negative molecular ions based on such radicals are not expected to be overly abundant. If we take as

0028-0836/81/080656—02$01.00

typical an abundance ratio[4-6] [A]/[AH] of $\leqslant 10^{-2}$ where AH is the stable species (for example, $A = C_5N$, $A^- = C_5N^-$, $AH = HC_5N$), then $[A^-]/[AH] \leqslant 10^{-3} - 10^{-4}$. Experimental work on the attachment of small free radicals is desirable to determine whether 10^{-3}–10^{-4} is a reasonable estimate or a severe upper limit. If the former assessment is correct, certain negative ions may eventually be detectable in dense interstellar clouds. Also if some relevant radiative attachment rates do approach 10^{-7} cm^3 s^{-1}, these and related processes must be included in detailed cloud models.

Massive neutrinos, helium production and the primordial magnetic field

Stuart L. Shapiro & Ira Wasserman

Center for Radiophysics and Space Research, Cornell University, Ithaca, New York 14853

Experimental evidence[1] for a non-zero neutrino rest mass, $m_\nu \neq 0$, while still controversial[2], poses intriguing cosmological questions[3-10]. One reassurance is that the possibility of non-zero masses does not necessarily alter previous predictions of the standard big-bang model for the primordial ^{4}He abundance, Y. We show here that a non-zero neutrino rest mass, $m_\nu \sim 10$ eV, may provide the most stringent upper limit proposed to date on the strength of any ordered, primordial magnetic field: $B_0 \leqslant 4\times10^{-9}/m_\nu$ (eV) G. This limit is set by requiring that previous predictions of the standard big bang model for the primordial ^{4}He abundance remain unaltered by the spin procession and subsequent thermalization of right-handed, as well as left-handed, Dirac neutrinos in the early Universe.

Massive neutrinos can be either Majorana or Dirac fermions. Majorana neutrinos are represented by two-component spinor wave functions that are CP eigenstates in the neutrino rest frame. As Majorana mass terms do not conserve lepton number there is no Majorana antineutrino. The total number of spin degrees of freedom per Majorana neutrino flavour is, therefore, $g = 2$, thus the same as for massless neutrinos. Dirac neutrinos, like electrons, are represented by four-component spinor wave functions that are C and P eigenstates in the neutrino rest frame. Dirac mass terms conserve lepton number, so there are both Dirac neutrinos and antineutrinos, and $g = 4$.

For Dirac neutrinos with $m_\nu \neq 0$, both left- and right-handed neutrinos could be present in the early Universe, thereby doubling the number of possible neutrino types. However, neutrino–fermion weak reactions mediated either by vector ($\mathbf{W}^\pm$, $\mathbf{Z}^0$) or scalar (Higgs) bosons through the standard Weinberg–Salam–Glashow[11-13] (WSG) model, extended to include Dirac neutrinos with $m_\nu \neq 0$, cannot maintain ν_R in thermal equilibrium at the critical decoupling epoch, $kT_D \sim 1$ MeV (refs 9, 10). In fact, ν_R decouple much earlier at $kT \gg 80$ GeV. Previous studies have shown[14] that, for a present-day baryon density $\rho_B \gtrsim 10^{-2}\rho_c$, any new relativistic particles in the early Universe must decouple at $kT \gtrsim 0.2$ GeV to satisfy the observational constraint on the ^{4}He abundance[15], $Y \leqslant 0.25$. So, as far as neutrino–fermion weak interactions are concerned, the WSG model extended to include massive neutrinos is consistent with this requirement.

A further consequence of non-zero neutrino rest masses is that neutrinos acquire a magnetic moment ($G_F \equiv 10^{-5} m_p^{-2}$),

$$\mu_\nu = \frac{3eG_F\hbar m_\nu}{8\sqrt{2}\pi^2 c} \tag{1}$$

from diagrams of electro-weak order[16,17]. Consequently, neutrinos can precess in an external magnetic field. Extremely relativistic neutrinos in the early Universe can flip helicities at a rate[16,17]

$$\Gamma_{LR}^{B} \approx \frac{2}{\pi}\frac{\mu_\nu B_\perp}{\hbar} \approx \frac{3eG_F m_\nu B_\perp}{4\sqrt{2}\pi^3 c} \tag{2}$$

where $B_\perp$ is the component of the primordial field perpendicular to the neutrino velocity. For a sufficiently large magnetic field, $\Gamma_{LR}^{B} \gtrsim \Gamma_{LL}$, where Γ_{LL} is the rate of neutrino–fermion interactions which thermalize the left-handed neutrinos. For such rapid flipping an equilibrium population of right-handed neutrinos can result, doubling the number of thermal (Dirac) neutrino types (from $N_\nu \gtrsim 3$ to $2N_\nu \gtrsim 6$). This would violate the constraint[14,15] of $N_\nu \leqslant 4$ imposed on the standard big-bang model by the observed ^{4}He abundance, $Y \leqslant 0.25$, for $\rho_B \gtrsim 10^{-2}\rho_c$. (If $\rho_B \ll 10^{-2}\rho_c$ the allowed number of neutrino types $N_\nu \gg 4$; a conservative lower limit[5] is $\rho_B \gtrsim 0.006\rho_c$.) Alternatively, satisfying the constraint $N_\nu \leqslant 4$ by requiring

$$\Gamma_{LR}^{B} \leqslant \Gamma_{LL} \tag{3}$$

up to ν_L-decoupling at $T_D \sim 1$ MeV places a surprisingly stringent limit on the strength B_0 of any present-day relic magnetic field.

Our limit is an immediate consequence of three basic assumptions:

(1) The standard big-bang model of nucleosynthesis in the early Universe[18,19] is valid and the primordial ^{4}He abundance satisfies[15] $Y \leqslant 0.25$.

This assumption requires inequality (3) to hold throughout the nucleosynthesis epoch. Enforcing this requirement at T_D, when $\Gamma_{LL} \sim \Gamma_{exp}$, where

$$\Gamma_{exp} \sim (G\rho)^{1/2} \sim \frac{(kT)^2}{\hbar^{3/2}c^{5/2}}$$

is the expansion rate and ρ is the total density of the Universe, gives

$$m_\nu B_D \leqslant \frac{4\pi^3\sqrt{2}}{3}\frac{G^{1/2}(kT_D)^2}{eG_F c^{3/2}\hbar^{3/2}}. \tag{4}$$

In equation (4) we have set $B_\perp \sim B_D$, the field strength at neutrino decoupling.

(2) The magnetic field remains 'frozen-in' to the perfectly conducting matter so that $BR^2 \sim$ constant, where R is the expansion parameter. Hence, BT^{-2} does not change as the Universe expands.

Because $\Gamma_{LR}^{B} \propto B \propto T^2$ while[18,19] $\Gamma_{LL} \propto T^5$, inequality (4) ensures that the population of ν_R cannot equilibrate for any $T > T_D$. Furthermore, if T_0 is the present temperature of the microwave background, then $B_0 = B_D(T_0/T_D)^2$, so inequality (4) gives

$$m_\nu B_0 \leqslant \frac{4\pi^3\sqrt{2}}{3}\frac{G^{1/2}(kT_0)^2}{eG_F c^{3/2}\hbar^{3/2}} \approx 3.9\times10^{-9} \quad \text{eVG} \tag{5}$$

for $T_0 = 2.7$ K (refs 18, 19).

0028-0836/81/080657—02$01.00

(3) The neutrino mass probably lies in the range

$$4 \leqslant m_\nu(\text{eV}) \leqslant 20 \qquad (6)$$

It has been argued[3-5] that neutrinos with masses in this range would solve the missing mass problem for clusters of galaxies without demanding unacceptably high mass-to-light ratios for individual and binary galaxies and small groups. For this mass range, inequality (5) implies

$$B_0 \leqslant \frac{4\pi^3\sqrt{2}}{3} \frac{G^{1/2}(kT_0)^2}{eG_F m_\nu c^{3/2}\hbar^{3/2}} \approx (0.2\text{–}1.0)\times 10^{-9} \quad \text{G} \qquad (7)$$

The right-hand side of inequality (7) is an interesting combination of fundamental microphysical and cosmological constants. Unlike many comparable expressions—such as the large numbers—the sole cosmological parameter, T_0, is not a major source of uncertainty in equation (7).

In deriving inequality (7) we have implicitly assumed that the magnetic field is uniform over all length scales $L \leqslant L_D \equiv ct_D \sim 3\times 10^{10}$ cm at decoupling, implying uniformity over length scales $L_0 \leqslant L_D z_D \sim 30$ pc at present. In the unlikely event that the field is actually tangled over smaller scales $l_0 \ll L_0$ today (and l_0/z_D at decoupling) the upper limit to B_0 is increased over the value given in equation (7) by the random-walk factor $(L_0/l_0)^{1/2} = (30\text{pc}/l_0)^{1/2}$.

Note that inequality (7) provides the most stringent limit on B_0 proposed to date. For example, invoking assumption (2) we find that the requirement that the magnetic energy density does not exceed the radiation energy density only implies

$$B_0 < (8\pi a)^{1/2} T_0^2 \approx 3.2 = 10^{-6} \quad \text{G} \qquad (8)$$

for a present black-body radiation temperature $T_0 \approx 2.7$ K. Because $B^2/\rho_B \propto T$, where ρ_B is the baryon mass density, inequality (10) also guarantees that the magnetic energy density remains below the baryon mass density throughout the matter-dominated era. Such a magnetic field is also much too weak to produce an observable anisotropy in the microwave background[20-22]. To guarantee $B^2/8\pi at^4 < 1$ all the way back to the very earliest epochs, assumption (2), leading to the inequality (8), must be modified by a logarithmic correction factor[23]. Thus, consider a Bianchi type I model with a uniform magnetic field for the anisotropic expansion of a perfectly conducting universe. Requiring that $B^2/8\pi aT^4 < 1$ back to the Planck time $t_p \sim (\hbar G/c^5)^{1/2} \sim 10^{43}$s demands[23]

$$B_0 < (1\text{–}3)\times 10^{-7} \quad \text{G} \qquad (9)$$

which is still far less restrictive than equation (7).

For $T \geqslant 1$ MeV, magnetic field strengths up to $\sim 10^2 \times (8\pi a)^{1/2} T^2 \sim 10^{15} T^2$ (MeV) cause at most a ~15% change in neutron producing and destroying weak reactions involving relativistic electrons and neutrinos[24]. Accordingly, ignoring spin precession, the major effect of a primordial B-field on cosmological nucleosynthesis arises from its influence on the expansion rate and anisotropy of the Universe. Previous limits on B_0 derived by assuming the validity of the standard big-bang model for cosmological nucleosynthesis with $m_\nu \equiv 0$ are therefore equivalent to inequalities (8) and (9).

Finally, if all or part of the Faraday rotation of a distant extragalactic radio source at redshift z can be attributed to a hypothetical ionized intergalactic medium with free electron density $n_{e,0}$ one gets a limit on $n_{e,0} B_0$ if the field is uniform[25-27], and on $n_{e,0}\sqrt{l_0}$ if the field is twisted with a coherence length l_0 (refs 28–30). In the case of a uniform field one obtains a rotation measure[27]

$$\text{RM} = \frac{e^3 n_{e,0} B_{\parallel,0}}{3\pi m_e^2 c^3 H_0 \Omega^2}[(1+\Omega z)^{3/2} - 3(1-\Omega)(1+\Omega z)^{1/2} - 3\Omega + 2] \qquad (10)$$

where $\Omega \equiv 8\pi G\rho_0/3H_0^2$, ρ_0 is the total mass density, $H_0 = 100h$ km s^{-1} Mpc^{-1} is Hubble's constant, and $B_{\parallel,0}$ is the line-of-sight component of the field. Observations[30] imply an intergalactic rotation measure $\leqslant 10$ rad m^{-2}, from which one gets (assuming $\Omega z \ll 1$)[25-27]

$$B_0 \leqslant 10^{-10}\Omega_e^{-1} h^{-1} \quad \text{G} \qquad (11)$$

for a uniform field out to $z \sim 2$, and

$$B_0 \leqslant 3\times 10^{-9}\Omega_e^{-1} h^{-1/2}[l_0(\text{Mpc})]^{-1/2} \quad \text{G} \qquad (12)$$

for a twisted field[30], where $\Omega_e \equiv 8\pi G n_{e,0} m_p/3H_0^2$. Nucleosynthesis calculations, assuming $N_\nu \geqslant 3$ and $Y \leqslant 0.25$, require $\Omega_B h^2 \leqslant 0.014$, where Ω_B is the present baryon density in units of the closure density[5,15]. Taking $\Omega_e \sim \Omega_B \sim 10^{-2} h^{-2}$, inequalities (11) and (12) imply

$$B_0 \leqslant 10^{-8} h \quad \text{G} \qquad (13)$$

for a uniform field, and

$$B_0 \leqslant 3\times 10^{-7} h^{1/2}[l_0(\text{Mpc})]^{-1/2} \quad \text{G} \qquad (14)$$

for a twisted field. Smaller electron densities give less stringent limits.

Comparing inequality (7) to inequalities (8), (9), (13) and (14) shows that the most severe constraint on any primordial magnetic field is a simple consequence of a finite neutrino rest mass. Specifically, the calculated magnetic moment[16,17], μ_ν, of massive, four-component Dirac neutrinos in the WSG $SU(2)_L \times U(1)$ theory of weak and electromagnetic interactions[11-13] imposes an upper limit on B_0 an order of magnitude or more lower than any previous limit. (Two-component Majorana neutrinos do not alter the standard nucleosynthesis calculations even when $B_0 \neq 0$ so they set no useful limit to B_0.) Even more stringent limits on B_0 could arise in manifestly left–right symmetric theories with spontaneous parity non-conservation[31], even if the neutrino rest masses are very small, $m_\nu \ll 1$ eV.

Density evolution of radio sources fuelled by stellar mass loss

M. E. Bailey & J. MacDonald

Astronomy Centre, University of Sussex, Falmer,
Brighton BN1 9QH, UK

At early cosmological epochs the comoving density of radio sources was very much higher than it is at present. Here we outline a theory for the evolution of the comoving density of radio sources, based on the hypothesis that mass loss from stars flows inwards in massive galaxies to fuel nuclear activity. We use a sufficient condition for the occurrence of inflow to show that the critical galaxy mass above which a total outflow becomes impossible decreases towards earlier epochs. We assume that the comoving density of radio sources is proportional to the comoving density of galaxies with inflow. The predicted density evolution of the radiogalaxy phenomenon is in good agreement with observations.

The evolution of stellar mass loss in galaxies heated by supernovae has been widely discussed[1–5]. In the special case of spherical symmetry, it can be shown[5] that a necessary condition for steady outflow beyond a stagnation radius r_s is

$$\alpha_{sn}E_{sn}(M_T - M_*(r_s)) \geq 2\pi r_s^3 \alpha P_*(r_s) + \alpha M_*(r_s)\left[\frac{GM_*(r_s)}{r_s} + \phi_*(r_s)\right] + \frac{3}{2}\alpha\int_{M_*}^{M_T}\frac{GM_*}{r}\,dM_* \qquad (1)$$

where α_{sn} is the specific mass loss rate due to supernovae, E_{sn} is the energy per unit mass of supernovae ejecta, M_T is the total mass of the galaxy, α is the specific stellar mass loss rate, $P_*(r) = \rho_* V^2/3$ is the effective pressure of the stellar velocity distribution and $\phi_*(r)$ is the gravitational potential. Adopting a de Vaucouleurs $r^{1/4}$ law[6] for the projected mass distribution of elliptical galaxies equation (1) becomes, in dimensionless form,

$$C \equiv \frac{\alpha_{sn}E_{sn}}{\alpha}\,\frac{r_e}{GM_T} \geq F_{crit}(x) \qquad (2)$$

where $x = r/r_e$ and r_e, is the effective radius. The function F_{crit} is shown for the de Vaucouleurs law in Fig. 1; it decreases monotonically from the value 0.5042 at the centre, to zero at infinity.

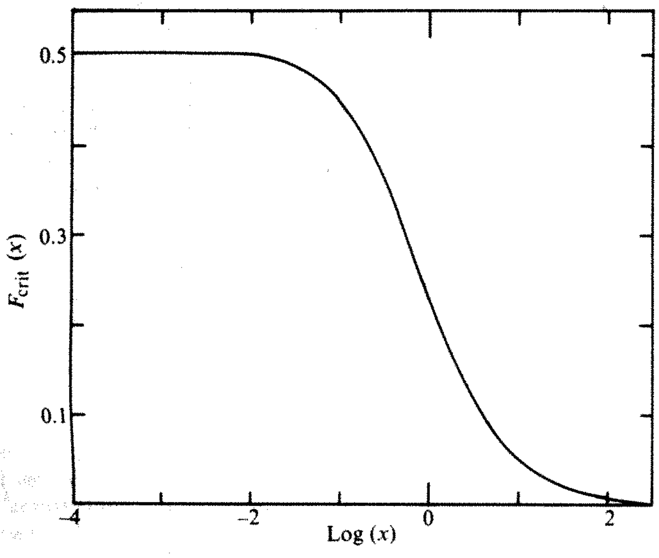

Fig. 1 The wind criterion function $F_{crit}(x)$ for the de Vaucouleurs $r^{1/4}$-law galaxy model is shown versus log (x), where $x = r/r_e$.

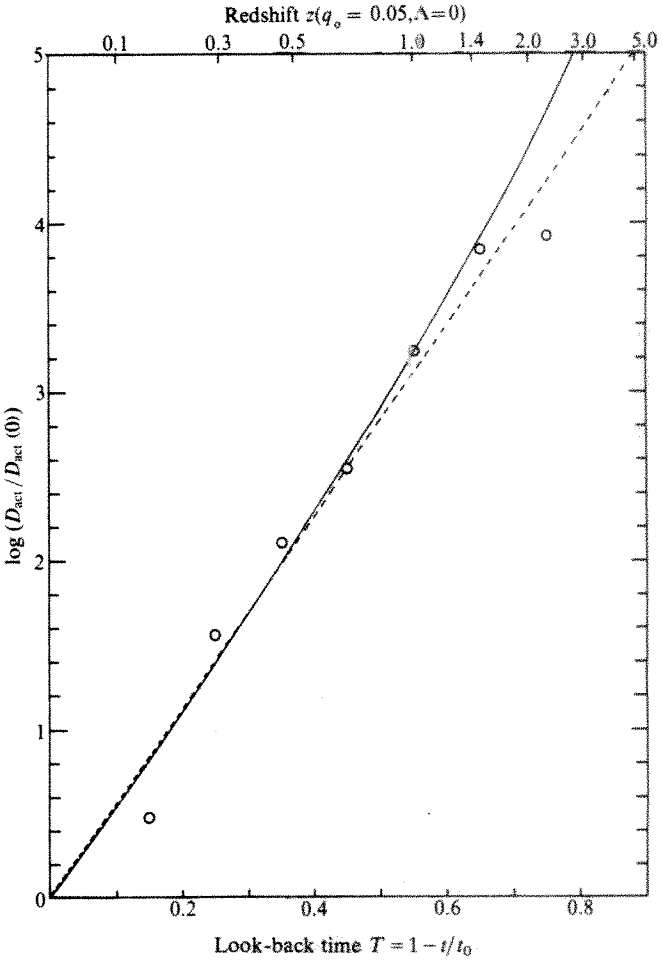

Fig. 2 The predicted comoving density of quasars is shown compared with the observations (○) and approximate analytic form (dashed line) given by Turner[19]. The predicted curve assumes $C_0 = 1.5$, $H_0 = 85$ km s^{-1} Mpc^{-1} and the luminosity function of Kirshner *et al.*[18].

We assume here that inflow occurs whenever conditions are such that total outflow (as indicated by equation (2) with $x = 0$) is not possible. This assumption favours outflowing winds and thus slightly underestimates the proportion of galaxies with inflow.

For practical use it is convenient to rewrite the quantity C on the left-hand side of equation (2) in terms of observable galaxy parameters. The specific mass loss rate $\alpha(t)$ can be obtained from a stellar population model of the galaxy[7]. For a Salpeter initial mass function we find[5] that a good approximation to $\alpha(t)$ is given by $\alpha \simeq 10^{-19}$ $(10^{10}\,\mathrm{yr}/t)\,\mathrm{s}^{-1}$. In principle, the specific supernova mass loss rate α_{sn} could also be obtained from the same stellar population model. In practice, however, uncertainties[8] in the nature of Type I supernovae make such a calculation of dubious validity. Here Type I supernovae are assumed to have low-mass progenitors[9] and are caused by mass transfer in low-mass binary systems[10]. In this case the supernova rate will change on the evolutionary time scale associated with such systems ($\sim 10^{10}$ yr). The difficulties in providing realistic estimates for the evolution of α_{sn} lead us to assume that α_{sn} is independent of epoch, consistent with the expectation of only slow change. Similarly we assume that the mean energy which Type I supernovae inject into the interstellar medium is also independent of epoch. Using the observed supernova rate for elliptical galaxies[11] $\nu_{sn} = 0.157\,h^2$ supernovae per $10^{10}\,L_\odot$ per 100 yr (where $h = H_0/50$ km s^{-1} Mpc^{-1}), and mean supernova energy 4×10^{43} J (ref. 12), we have $\alpha_{sn}E_{sn} = 10^{-8}(L_T/10^{10}L_\odot)(10^{11}M_\odot/M_T)h^2$ J kg^{-1} s^{-1}.

We now express M_T and r_e/GM_T in terms of galaxy luminosity. An empirical relation connecting the B surface

0028-0836/81/080659—03$01.00

brightness of a galaxy at r_e with the effective radius r_e has been found by Kormendy[13]:

$$\mu_B(r_e) = \left[3.02 \log\left(\frac{r_e}{1\ \text{kpc}}\right) + 19.74 - 3.02 \log(h)\right] B \text{ mag arc s}^{-2} \tag{3}$$

Combining this with the theoretical relationship between the absolute magnitude of a de Vaucouleurs galaxy, r_e and $\mu(r_e)$:

$$M_B = -39.96 + (\mu_B(r_e)/1 \text{ mag arc s}^{-2}) - 5 \log\left(\frac{r_e}{1\ \text{kpc}}\right) \tag{4}$$

gives $L_B = L_{B,K} h^{x_1} (r_e/1\ \text{kpc})^{x_2}$, where the empirically determined constants are $x_1 = 1.208$, $x_2 = 0.792$ and $L_{B,K} = 9.5 \times 10^{35}$ W.

A second empirical relationship found for elliptical galaxies is the $L - \sigma^4$ correlation, connecting luminosity with observed central line-of-sight velocity dispersion. Using the particular form found by Terlevich *et al.*[14]:

$$\log\left(\frac{\sigma}{1 \text{ km s}^{-1}}\right) = -0.0959 M_B + 0.328 + 0.4795 \log(h) \tag{5}$$

we find $L_B = L_{B,T} h^{-2} (\sigma/100 \text{ km s}^{-1})^{x_3}$, where $x_3 = 4.171$ and $L_{B,T} = 7.3 \times 10^{34}$ W. Finally we use the theoretical relation between σ and M_T/r_e, given[15] for small finite apertures by

$$\sigma^2 \simeq 0.2\, G M_T / r_e \tag{6}$$

Expressing B-luminosities in terms of the characteristic luminosity L_B^* which occurs in luminosity functions of the form proposed by Schechter[16], and defining $L_B^* = L_{B,n}^* h^{-2}$, we thus obtain

$$M_T(l) = 1.2 \times 10^{10} \left(\frac{L_{B,n}^{*x_5}}{L_{B,T}^{2/x_3} L_{B,k}^{1/x_2}}\right) h^{-(x_4 + 2x_5)} l^{x_5} M_\odot \tag{7}$$

where $x_4 = x_1/x_2 - 4/x_3 = 0.566$, $x_5 = 1/x_2 + 2/x_3 = 1.742$ and $l = L_B/L_B^*$. This implies (using our adopted parameter values) $M_T/L_B \propto M_T^{0.43}$ in good agreement with data presented[17] by de Vaucouleurs.

Combining these relations, the wind criterion equation (2) can be expressed directly in terms of the present value of the dimensionless luminosity l, cosmological epoch t, and other observable quantities. We find, for outflow beyond radius x

$$C \equiv C_0 h^{(2+x_1)/x_2} l^{-(1/x_2 + 4/x_3 - 1)} \frac{t}{t_0} \geqslant F_{\text{crit}}(x) \tag{8}$$

where t_0 is the present epoch, and the constant C_0 depends entirely on presently observed quantities such as t_0, $\alpha(t_0)$, $\alpha_{sn} E_{sn}(t_0)$, $L_{B,K}$, $L_{B,T}$, $L_{B,n}^*$ and the ratio L_T/L_B of total-to-blue luminosity. (This arises from the definition[11] of ν_{sn}.) Adopting for this last factor the reasonable value of 10, and taking[18] $L_{B,n}^*$ to correspond to an absolute blue magnitude $M_{B,n}^* = -21.0$, we obtain $C_0 \simeq 1.5$, showing that this coefficient is of the order of unity. The value of C_0, although uncertain, can in principle be determined entirely by independent observations; the time-dependence shown in equation (8) comes from the assumed time-dependence of $\alpha_{sn} E_{sn}/\alpha$ as discussed above.

Inverting equation (8) we find that at epoch $\tau = t/t_0$ all galaxies with luminosity exceeding $l_c(\tau)$ will have non-zero stagnation radii, where

$$l_c(\tau) = (C_0/F_{\text{crit}}(0))^{x_6} h^{x_7} \tau^{x_6} \tag{9}$$

and $x_6 = 1/(1/x_2 + 4/x_3 - 1) = 0.819$ and $x_7 = (2 + x_1) x_6 / x_2 = 3.316$.

The luminosity function for elliptical galaxies is similar to that of the general field[18]. We therefore assume a Schechter luminosity function defined so that the number of galaxies per unit volume with luminosities in the range $(L, L + \mathrm{d}L)$ is

$$\phi(L)\mathrm{d}L = (\phi^*/L^*)(L/L^*)^a \exp(-L/L^*)\mathrm{d}L$$

The comoving density of galaxies with non-zero stagnation radii normalized to the present epoch $\tau = 1$ is thus given by

$$D(\tau) = n(\tau)/n(1) \tag{10}$$

where

$$n(\tau) = \phi^* \int_{l_c(\tau)}^{\infty} l^a \exp(-l)\, \mathrm{d}l \tag{11}$$

On our model, in which inflowing stellar mass loss fuels active galactic nuclei, we expect the number density of radio sources at any epoch to be proportional to $n(\tau)$. Thus $D(\tau)$ also describes the comoving density of active galaxies, D_{act}.

Observationally it is found[19] that the comoving density of quasars is well fitted by an exponential in look-back time $T = 1 - \tau$, given by $D_{\text{obs}} \simeq \exp(13T)$. Figure 2 shows these observations compared with the prediction of our model using parameters $C_0 = 1.5$ (see above), $H_0 = 85$ km s^{-1} Mpc^{-1} (refs 20, 21) and luminosity function exponent $a = -1.10$ (ref. 18). The predicted curve is insensitive to choice of a, but is more critically determined by C_0, H_0 and $F_{\text{crit}}(0)$ through the relation (equation (9)) $l_c(1) \simeq 14$. An equally good fit to the data is obtained for other values of C_0 and H_0 provided $l_c(1)$ is approximately unchanged; for example good fits are also obtained with $(C_0, h) = (0.7, 2), (11.0, 1)$.

Assuming that inflowing stellar mass loss produces nuclear activity with luminosity given by $P = \eta c^2 \alpha(t) M_*(r_s(t))$ (for example, by accretion from a disk onto a massive black hole), we can use the present theory to predict the comoving luminosity function of active nuclei at various epochs. Figure 3 shows the results of such a calculation, made using $\phi^* = 2.35 \times 10^{-3}$ h^3 galaxies (Mpc)$^{-3}$ and energy generation efficiency factor $\eta = 0.3$. (The shapes of the comoving function do not depend on either ϕ^* or η.) The predicted luminosity function is in encouraging agreement with that indicated by observations[19], although a detailed comparison is not possible due to the lack of spectral information in such a simple model.

Finally, we have also calculated the numbers of galaxies with inflow as a function of redshift z for an open $q_0 = 0.05$ model

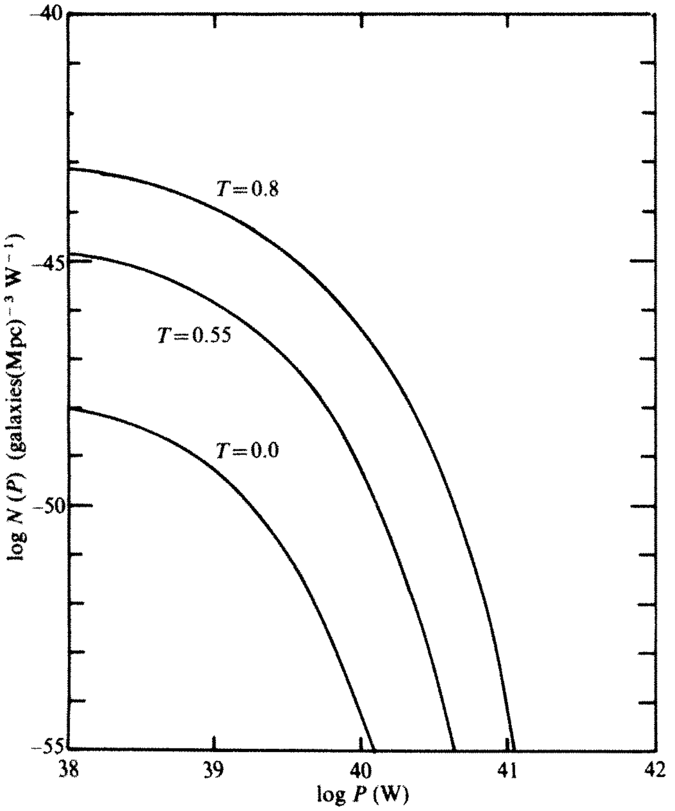

Fig. 3 The predicted co-moving bolometric luminosity function for an accreting black hole model, for three values of the look-back time T.

universe. The predicted counts can be fitted approximately by a powerlaw $N(<z) \simeq 1.5 \times 10^4 z^{5.85}$. The total number of sources out to redshift $z = 4$ is $\sim 5 \times 10^7$, consistent with counts of faint objects[22].

We conclude that the present theory apparently explains the large increase in comoving density of radio sources towards early epochs. At present only massive elliptical galaxies ($L \geq 10L^*$) should be radio sources. At earlier times, because of the higher stellar mass loss rate, less massive ellipticals cannot sustain total outflow. The absence of gas in moderately massive ellipticals may thus be a relatively recent phenomenon. On this model the reason for a rapid increase in comoving density of radio sources (by factors $\geq 10^3$ over a Hubble time) is principally the steepness of the luminosity function at $L > L^*$. This means that small evolutionary changes in l_c greatly affect the source counts. Whatever the nature of the central source of activity, the present work supports the hypothesis that nuclear activity in elliptical galaxies is caused by inflowing stellar mass loss.

We thank Professor R. J. Tayler and Dr R. C. Smith for helpful comments. This research was supported by the SRC.

Thermal-mechanical properties of a monomolecular film detected by a vibrating reed

R. H. Lacombe & B. M. J. Kellner

International Business Machines Corporation, East Fishkill Facility, Hopewell Junction, New York 12533

Thin films of organic materials are finding many applications in modern technology. The microelectronics industry, in particular, uses very thin organic films both as photoresists and as insulating layers. The ultimate in organic thin films is represented by molecular monolayers of the order of 2.0 nm thick as deposited by the Langmuir–Blodgett technique[1]. By adapting a vibrating reed apparatus[2] we have investigated the thermal–mechanical properties of a supported 6-nm thick monolayer film. Although a monolayer melting transition could not be found in the resultant spectra, at least two other, low-temperature peaks (at −150 and −20 °C) were detected which seem to be due to relaxation processes both within the film as well as at interfaces of the monolayer structure. Our main aim was to determine whether the mechanical properties of ultrathin films could be measured by the vibrating reed technique, and to detect any thermal–mechanical relaxations which may occur in such films, in particular whether or not a melting transition could be detected at elevated temperatures. Such thermal–mechanical measurements have long been used in the plastics industry to characterize the mechanical properties of resin materials in bulk. The vibrating reed technique may provide an analogous service for very thin organic coatings.

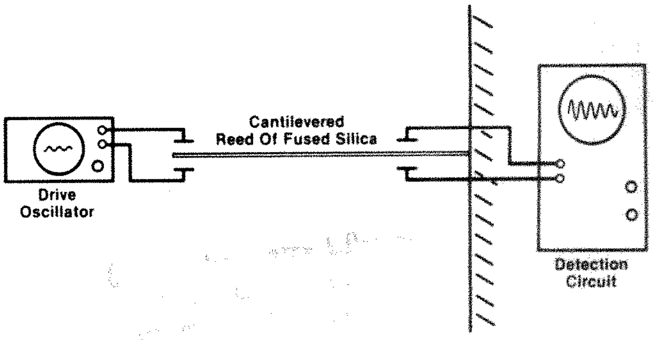

Fig. 1 The vibrating reed apparatus. The silica reed is used as a substrate to support thin films whose mechanical properties are to be investigated.

Other recent work in thin film mechanical spectroscopy has investigated freely suspended liquid crystal films using a disk and support ring apparatus[3–5]. Also the superfluid transition of ^{4}He has been studied using mylar as a substrate[6]. The vibrating reed technique supplements these methods by covering a wide range of temperature and frequency and by not being restricted to monolayer forming films.

Figure 1 gives a schematic representation of the vibrating reed apparatus which is described in detail in ref. 2. The basic concept is: a cantilevered reed is excited into vibration by a set of drive electrodes connected to a suitable oscillator; a corresponding set of detection electrodes, positioned approximately one-third of the way up from the base (a position which avoids setting the electrodes at a vibration node) is used to monitor the amplitude of vibration.

First the reed is excited to a given amplitude and then the drive signal is switched off and the free decay of the reed vibration is monitored. Theoretically, there is an infinite number of modes of vibration into which the reed can be excited by appropriately adjusting the drive frequency. In practice, one works with the first dozen or so lowest tones. The dynamic modulus of the reed material is directly related to the frequency of vibration at any given tone, and the internal friction of the material is inversely proportional to the number of cycles taken for the amplitude to decay to one-half of its initial value. The precise details on measuring these quantities are given in ref. 2.

In the present experiment, a composite sample is used. It consists of a reed-like substrate of fused silica, ~50 μm thick. When operating under a vacuum $\sim 10^{-6}$ torr, the internal friction of the fused silica substrate is exceedingly low over a wide temperature range. This characteristic allows the internal friction of coatings to be detected which may be even 1,000 times thinner than the substrate itself.

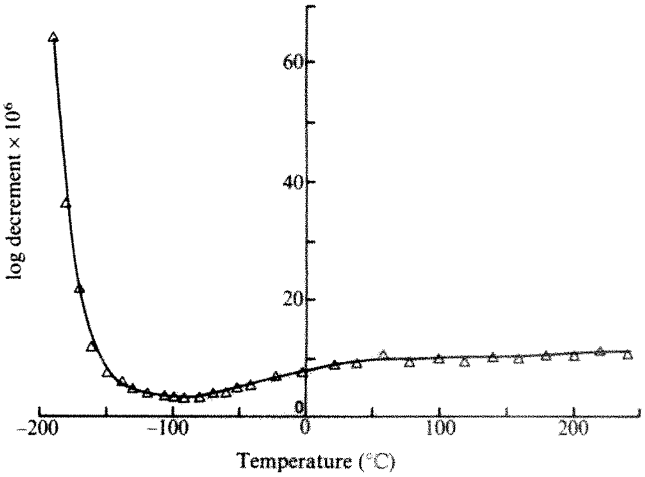

Fig. 2 Plot of internal friction of fused silica from −190 to 240 °C. Note the low and slowly varying behaviour of the internal friction above −150 °C. The solid line was obtained through a piecewise least-square polynomial fit to the data.

0028-0836/81/080661—02$01.00

Figure 2 shows the internal friction of fused silica from liquid nitrogen temperature to 240 °C. Note the relatively flat and low internal friction behaviour above −150 °C. Below −150 °C, fused silica shows a large internal friction peak[7] which would make it an unsuitable substrate material in this temperature range. Above −150 °C, however, the internal friction is around 10^{-5}, which implies that typically 10^5 cycles are required for the blank reed to decay to half of its initial amplitude. The solid line in Fig. 2 was used to interpolate the experimental data so that the contribution of the bare substrate to the internal friction of the composite sample could be subtracted accurately and consistently.

An automated Langmuir trough was modified for Langmuir–Blodgett deposition[8]. Constant pressure conditions during dipping were maintained by an electric feedback circuit between the surface pressure monitor and the drive for the movable barrier of the trough. Arachidic acid was spread on an aqueous substrate of 3×10^{-4} M cadmium chloride buffered with 5×10^{-4} M sodium acetate and adjusted to *p*H 6 by the addition of small amounts of acetic acid and/or sodium hydroxide. The film was then compressed to 30 mN m^{-2} and transferred by the Langmuir–Blodgett technique onto a fused silica reed which had been scrupulously cleaned. A film composed of three monolayers of cadmium arachidate[9] on each side of the reed was built up. A fatty acid salt deposited in this way has been shown[10] to be composed of a molecular array in which the alkane chains are close-packed and the metal ions are sandwiched between the carboxyl groups of adjacent monolayers.

Figure 3 summarizes the primary experimental results of this work showing the internal friction of the built-up monolayer film as a function of temperature. The data represent three separate runs where the sample was heated to progressively higher temperatures to see if a melting transition could be detected. Such a transition in cadmium arachidate would be expected to occur at ~140 °C. This expectation is based on an extrapolation from the electron diffraction and frictional data reported by Bowden and Tabor[11]. The high-temperature data, however, showed only a flat baseline behaviour similar to that for the bare reed (see Fig. 2).

We conclude that material from the upper layers of the three-layer film simply sublimed away at the higher temperatures. Therefore no phase transition to a liquid form was observed. However, Fig. 3 clearly shows that there are at least two distinct dispersion peaks at the lower temperatures −150 and −20 °C, respectively. The dramatic decrease in the amplitude of the peak near −150 °C after successive heatings to higher and higher temperatures would seem to indicate that this peak is due to relaxation processes occurring in the bulk of the composite film. The higher temperature peak near −20 °C, however, shows a significantly less decrease in amplitude due to heat treatment. This peak may in fact be due to relaxations occurring at the interfaces of the monolayer structure (either monolayer–monolayer or monolayer–silica). This would also be consistent with the much lower intensity of this peak compared with the one near −150 °C. Figure 4 gives an expanded representation of the mechanical spectrum near −20 °C.

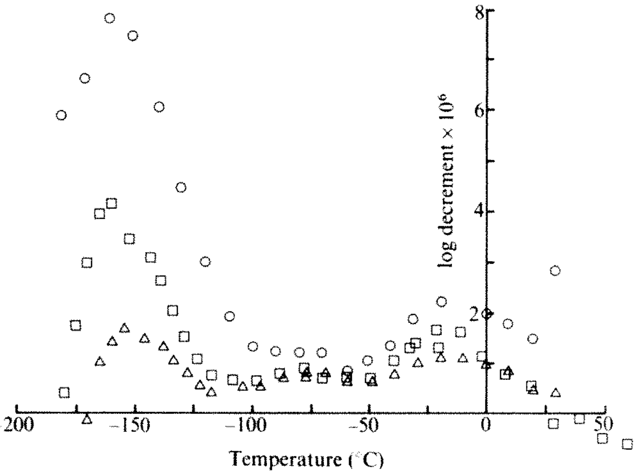

Fig. 3 Internal friction of three molecular layers of cadmium arachidate: ○, heated to 130 °C; □, heated to 160 °C; △, heated to 250 °C. Two dispersion peaks are clearly visible near −150 °C and −20 °C. This plot was obtained by subtracting the internal friction of the bare reed substrate from that of the coated reed. However, a correction factor should be included which depends on the modulus of the substrate and the film and also accounts for the difference in thickness of the two. As there was no way to obtain a reasonable estimate of the modulus of the monolayer film, the data are only proportional to the true internal friction of the film. (See ref. 2 for further details.)

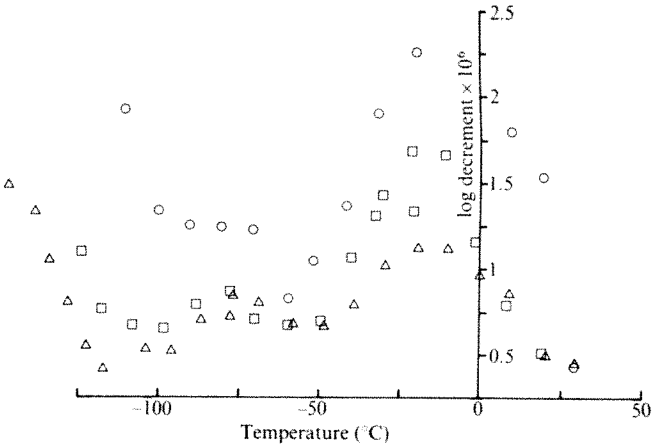

Fig. 4 Expanded view of Fig. 3 near −20 °C. A peak seems to be emerging near −75 °C for the samples which were heated to 160 and 250 °C.

The data in Figs 3 and 4 must be treated with caution as an exceedingly small amount of material is being dealt with, and there are no corroborative data on similar types of samples. However, these data may be clarified by comparison with another physical system which involves long hydrocarbon chains, for example, bulk polyethylene. Low density polyethylene also exhibits two low-temperature transitions near −100 °C and −10 °C respectively. The peak near −100 °C (referred to as the γ peak) seems to occur in polymers with five or more CH_2 units in series and is usually associated with amorphous or interfacial regions in semicrystalline systems. The peak near −10 °C (known as the β peak) is also associated with crystalline imperfections or possibly grain boundaries[12]. These observations support our conclusions if one remembers that our sample film thickness of 6 nm is about the size of an 'interfacial' region in a bulk polymer. Although these conclusions are preliminary, the fact that clear, reproducible spectra can be obtained indicates that the vibrating reed technique has a strong potential as an analytical tool for the study of the mechanical properties of ultrathin films.

Grain boundary microchemistry and stress-corrosion failure of mild steel

E. D. Hondros & C. Lea

National Physical Laboratory, Teddington, Middlesex TW11 0LW, UK

A common cause of failure of large metallic components is stress corrosion, often in subtle combination with fatigue. In the case of carbon steel as used in pipelines, the problem of understanding the cause of variations in susceptibility to intergranular stress corrosion between steel batches of apparently similar origin, history and operating conditions has been researched for many years. We report here the results of investigations including Auger electron spectroscopy which show that the source of variable behaviour is probably the differences in the microchemical content of grain boundary paths, differences which may easily exist between one batch or another of apparently similar steel.

Pure iron is resistant to stress corrosion cracking in nitrate environments, and although attempts have been made to trace the effects of a large number of alloying element additions, such as carbon, aluminium, chromium and nickel, there is apparently little systematic behaviour reported[1,2]. Most previous studies have been carried out on steels containing the usual amounts of the normal individual impurities common to commercial steel stock. Our present investigations suggest that the lack of reproducibility in the reported effects could be due to differences in heat treatment and impurity contents.

Previous Auger electron spectroscopy measurements[3] established that different impurity elements may enrich grain boundaries and other interfaces by factors between 1 and 10^5. Thus, on the assumption (later confirmed experimentally) that impurity elements at low bulk levels do not affect mechanical properties such as yield stress, we undertook a direct study of the microchemistry of the grain boundaries to investigate whether a correlation between susceptibility and bulk impurity content exists.

The test specimens were prepared from 11 ingots of high purity 0.1% C mild steel (Table 1). In 10 of these alloys, the free residual sulphur was tied up chemically and rendered harmless by the addition of 0.05% Mn. To these ingots, a known, small quantity of one commonly occurring impurity element was added separately at that particular bulk level calculated to give rise to a grain boundary segregation content of about 20% of a monatomic layer following an isothermal heat treatment of 100 h at 600 °C. This treatment does not affect the microstructure nor the bulk properties but allows the 20% monolayer segregation to be attained from bulk impurity levels comparable with those encountered in commercial stock. The additions were: 0.3% Al, 0.15% As, 0.01% Ca, 0.1% Cu, 0.3% Ni, 0.03% P, 0.08% Sb, 0.1% Sn and 0.2% Zn. The amount of bulk additive sufficient in each case to produce this 20% monolayer segregation was calculated on the basis of a correlation against maximum solid solubility established earlier[1]. From this, the grain boundary enrichment ratio β_N in a dilute binary alloy is given, within the limits,

$$\beta_N = \frac{1 \text{ to } 10}{X_N} \qquad (1)$$

where X_N is the solid solubility limit of element N and β_N is the concentration of the solute in the boundary at equilibrium compared with that in the bulk.

While such quantities were required in advance as part of the experimental design, the predicted segregation levels were later confirmed by exposing the grain boundaries in the spectrometer to direct analysis. In most cases this was difficult, because the levels of impurities were so low that they did not induce sufficient low temperature brittleness to allow exposure of the boundaries by *in-situ* fracture. The successful procedure was to

arrest the stress corrosion tensile test before rupture and to transfer the sample from the corrosive solution into the spectrometer, where the fracture was completed by low temperature impact in the ultra-high vacuum. By this process, the pre-existing intergranular stress corrosion crack sometimes extended up to one grain into the virgin steel before the fracture continued in a cleavage mode. These freshly exposed grain boundaries could be isolated and analysed, yielding the actual quantity of segregant on the grain boundaries before stress corrosion failure. Figure 1*a* shows that the stress corrosion crack was heavily oxidized and contaminated by exposure to air and the vacuum environment of CO. Figure 1*b* shows the intergranular fracture surface exposed within the spectrometer and immediately analysed, revealing here a tin segregation and Fig. 1*c*, the remainder of the fracture, which is transgranular and hence shows essentially only iron. The carbon Auger electron signal is associated with monolayer adsorption of CO from the vacuum environment and not with bulk carbon. This is demonstrated by the removal characteristic during ion sputtering of the fracture surface. Using quantification procedures for submonatomic layers, the segregation levels of the added impurities are expressed in terms of fractional adsorbed monolayers, X_B, on the grain boundaries. Table 1 confirms the ~20% level predicted by application of equation (1), within the limits of the equation.

The samples were hot rolled into standard specimen blanks and heat treated in air at 800 °C for 2 h, followed by the isothermal segregation treatment. Flat, unnotched tensile specimens were prepared and tested to failure in an environmental cell of flowing NH_4NO_3 (5M) solution with parallel control tests in a stable environment of liquid paraffin at 80 °C, all at a constant strain rate of $2\times10^{-6}\ s^{-1}$. A similar set of experiments were carried out in constant load testing conditions on a four-point bend rig, submerged in a static bath of the same solution.

The results of the constant strain rate tests are shown in Fig. 2. The error bars in the plotting values indicate the spread in data over six to eight measurements. Every specimen type exhibited stress corrosion in the nitrate environment, failing in a time shorter than that in the control environment. The additions, Zn, As, Sb, Ni and Sn, have a minor effect in reducing rupture lives, Cu, Ca and Al have a modest effect, while S and P clearly have the greatest influence. In the nitrate solution, fracture was predominantly and often entirely, intergranular, while in the control solution, ductile fracture occurred. Table 1 shows the average times to failure in the nitrate solution compared with those in the control solution (corrosive–inert ratio, R). Not only are the yield stresses of all the samples within the range $220\ MN\ m^{-2}\pm5\%$, but Fig. 2 shows that the minor impurity additions (as reflected in the times to failure in the inert environment), have not introduced any significant secondary effects on mechanical properties.

We present the results in terms of the change in R, in the analytical form:

$$-\Delta R = 20\mathrm{P} + 1.9\mathrm{Cu} + 1.0\mathrm{Sn} + 0.9\mathrm{Sb} + 0.4\mathrm{As} + 0.3\mathrm{Zn} + 0.2\mathrm{Ni} + (700\mathrm{S} + 27\mathrm{Ca} + 1\mathrm{Al}) \quad (2)$$

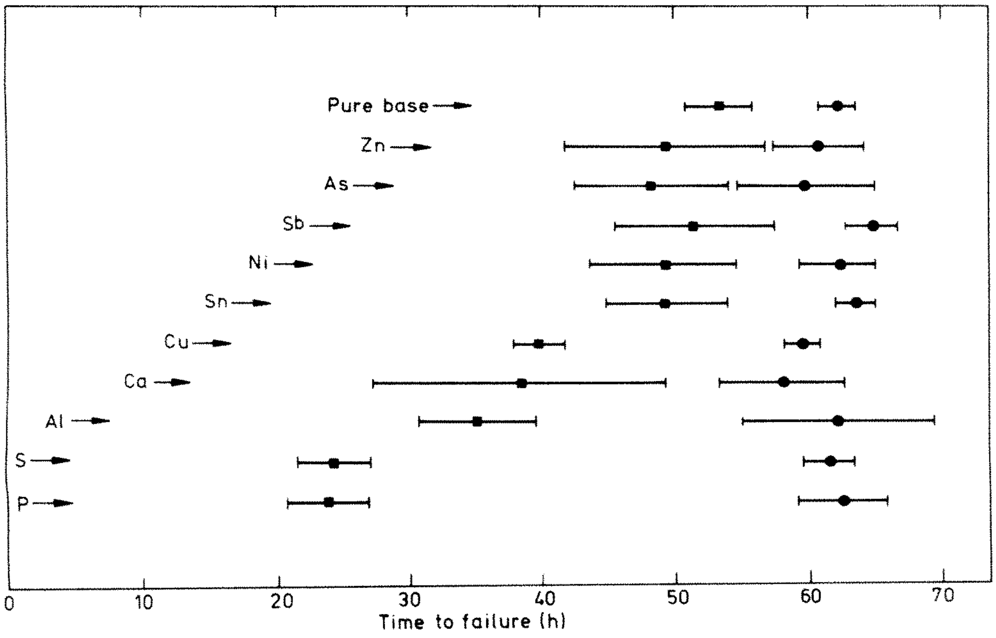

Fig. 2 The fracture times of the 11 alloys stress corroded at a constant strain rate. ●, Tests in paraffin; ■, tests in NH_4NO_3 solution.

Here, the element symbols represent the bulk content in weight per cent. By introducing the measured enrichment ratio β_N, the changes in R are presented in terms of the bulk concentration of the elements, thus providing a ranking order of potent segregating impurities. In commercial steels, S, Ca and Al are mopped up as precipitates and do not have a segregation role. Thus, to optimize the performance of carbon steels in nitrate environments, ΔR must be minimized. This can be achieved by reducing the bulk impurity levels of the first few elements, but in particular, that of residual phosphorus.

The detrimental influence of phosphorus on the stress corrosion properties of mild steel has been shown by Rädeker and Mishra[4] who added phosphorus in the range 0.012–0.12% to a pure base stock. By using the free energy of segregation obtained from our data, these bulk P levels can be readily transposed to grain boundary segregation levels and the correlation of these X_B values with stress corrosion properties is very similar to that reported here.

We have tried to rationalize the present results in terms of a mechanism whereby a galvanic potential is sustained and the grain boundary is exposed by preferential dissolution of atoms from the boundary. In an oxidizing environment such as aqueous ammonium nitrate, the driving force for atomic dissolution is related to the potential difference between the matrix and the segregants forming a galvanic cell. The hierarchy of the measured differences in the corrosive–inert ratio (ΔR) between each alloy and that of the pure base, normalized to a grain boundary concentration of 1% monolayer, bears a close resemblance to the order of the differences ΔE_0 between the equilibrium potentials of each segregant and that of iron. The potency of each added element for promoting stress corrosion cracking thus increases as $|\Delta E_0|$ increases. The coefficients of other elements, not shown in Fig. 2 or equation (2) can, therefore be predicted approximately as the product of the difference in equilibrium potential from that of iron and the grain boundary enrichment of the element[5]. Thus, although Al, Ti and Ca, for example, all have large values of ΔE_0 they do not segregate, their β values are low, and are therefore not harmful. (Indeed their addition may be beneficial by scavenging those elements which do readily segregate.) Thus, the application of the difference in equilibrium potential plus the grain boundary enrichment factor, seems an adequate first test for sensitivity of a particular element in intergranular stress corrosion.

Controls on low-stress hydro-fracture dilatancy in thrust, wrench and normal fault terrains

Richard H. Sibson

Department of Geology, Imperial College, London SW7 2BP, UK

Arrays of parallel extension fractures and veins are sometimes associated with exhumed faults and seem to be the product of repeated hydro-fracturing under a shared stress regime. Here theoretical considerations are used to suggest that this type of hydro-fracture dilatancy is essentially a low differential stress phenomenon. It may develop under hydrostatic fluid pressures around normal faults at shallow depths, but can only occur in association with thrusts when fluid pressures exceed the lithostatic load. This contrasts with most existing models for dilatancy, where the effects only become pronounced at high stress levels and are best developed around thrust faults.

Pre-failure dilatancy, leading to the redistribution of fluids, is a possible cause of observed precursors of shallow earthquakes[1,2], although the extent to which fluid migration is necessarily involved has been questioned[3]. Both the size of the dilatant zone and its stress-dependence are affected by the various types of dilatancy which can occur[4]. However, dilatant effects are commonly attributed to the opening of microcracks under high differential stresses. This accords with the more widespread recognition of earthquake precursors in association with thrust faults, where high stress levels may be characteristically expected[5] and subhorizontal extension cracks may open vertically without restraint[6].

The origin of an observable form of macroscopic fracture dilatancy which is sometimes found around ancient, exhumed faults (Figs 1 and 2*a*) is considered here. The arrays of parallel extension fractures or veins bear a systematic relationship to the faults in accordance with their slip-sense, which suggests that they formed in the same stress field. For example, in Fig. 1, vertical extension veins infilled with fibrous gypsum are associated with parallel-striking normal faults which disrupt a flat-lying sequence of Neogene shales and sandstones at Konarak in south-east Iran[7]. Both sets of structures are compatible with a regime where the maximum principal compressive stress, σ_1, is vertical and the least compressive stress, σ_3, is horizontal and perpendicular to strike. Where such extensional veins abut onto faults they are known as 'feather veins'[8,9]. The vein-fills usually consist of hydrothermal minerals which have grown inwards as fibres from the walls towards a median parting, the texture characteristic of a progressively opening fissure[10]. In many cases, a history of incremental opening is apparent[11], the implication being that fluid flow occurred intermittently with each episode terminating as deposition of hydrothermal minerals destroyed fracture permeability. Self-sealing of fractures in this manner is an important process controlling permeability in active hydrothermal systems[12].

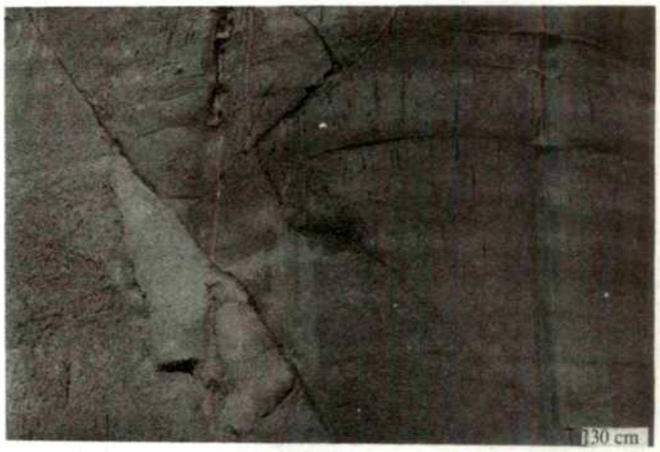

Fig. 1 Conjugate normal faults associated with vertical, gypsum-filled extension veins, Konarak, Makran Coast of south-east Iran. Clastic sandstone dykes (one occurs by the hammer) cut across the gypsum veins before feeding onto the faults.

These textural characteristics, coupled with the typically high length to thickness ratios, suggest that such veins are the product of repeated hydraulic extension fracturing[13]. Similarly oriented barren extension joints may also have formed by hydro-fracturing, but do not retain evidence for more than one episode of opening. Deposition of hydrothermal minerals ensures that some permanent dilatant strain results; at Konarak this locally exceeds 10^{-2} close in to the faults but the veining dies out 100 m or so to each side. From the presence of gypsum, implying temperatures <50 °C (ref. 14), and the observation that at least one of the normal faults displaces overlying Quaternary raised

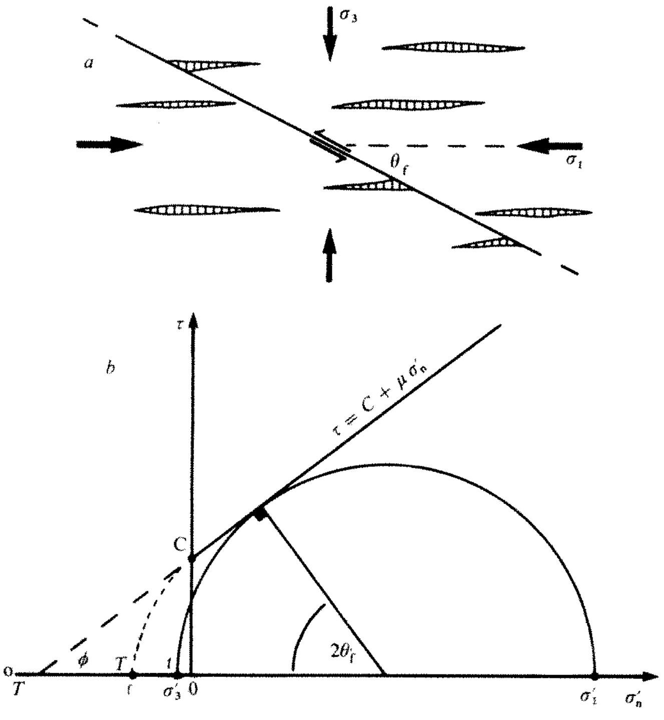

Fig. 2 Hydraulic extension fracturing in association with faults: *a*, field relationships; *b*, critical stress condition for simultaneous shear failure and reopening of extension fractures.

beaches[7], the vein arrays at Konarak have clearly developed in near-surface conditions. However, similar arrays with quartz or calcite as the usual vein filling may occur throughout the frictional regime occupying perhaps the top 10–15 km of quartzo-feldspathic crust[15]. Indeed, Ramsay[11] has attributed extension veins showing multiple increments of opening and sealing (>500 in one case) to repeated hydro-fracturing in upper greenschist facies conditions.

To examine the conditions in which cyclic hydro-fracture dilatancy can occur adjacent to an intermittently slipping fault, the case of an existing fault and extension fracture array in otherwise homogeneous rock is considered (Fig. 2*a*). The simple law of effective stress[16] is assumed to hold so that effective normal stresses are given by

$$\sigma_n' = \sigma_n - P \qquad (1)$$

where σ_n is the applied normal stress and P is the pore fluid pressure. Effective principal compressive stresses are thus $\sigma_1' > \sigma_2' > \sigma_3'$, and failure criteria can be represented on a Mohr plot of shear stress, τ, versus σ_n' (Fig. 2*b*). In the compressional field, shear failure along the fault is taken to be governed by a frictional criterion of Coulomb form,

$$\tau = C + \mu\sigma_n' \qquad (2)$$

where C is the cohesive strength of the fault and the coefficient of friction $\mu = \tan\phi$, ϕ being the angle of friction. The fault is also assumed to be oriented at the optimum angle to σ_1 for frictional sliding, so that $\theta_f = 45° - \phi/2$. Equation (2) may then be rewritten in terms of the effective principal stresses at failure[15] giving

$$\sigma_1' = 2K^{\frac{1}{2}}C + K\sigma_3' \qquad (3)$$

where $K = ((1+\mu^2)^{1/2} + \mu)^2$. A reasonable value[5] of $\mu = 0.75$ gives $\phi = 37°$, $\theta_f = 27°$ and $K = 4$. The extension fractures or veins are assumed to have a 'healed' tensile strength, t, which is less than the tensile strength of the intact rock, T, and is also small in comparison with C (strictly, $t < \frac{1}{2}C$ for $\mu = 0.75$), so that shear failure is restricted to the compressional field. Thus the condition for reopening the extension fractures is

$$\sigma_3' = -t \quad \text{or} \quad P = \sigma_3 + t \qquad (4)$$

Hydraulic fracturing, requiring $\sigma_3' < 0$, can only occur when $C > 0$. Thus, hydro-fracturing should not develop adjacent to cohesionless faults. However, natural faults are likely to possess a small cohesive strength through a combination of surface roughness and hydrothermal cementation. Its value is unlikely to exceed 10 bars (ref. 17) unless cementation is marked, in which case it may approach the cohesive strength of intact rock, perhaps 100 bar. If the opening of hydraulic fractures accompanies faulting, an important constraint is placed on the prevailing level of differential stress. From Fig. 2*b* and equations (3) and (4), the critical differential stress for simultaneous shear failure and hydro-fracturing is

$$\begin{aligned}(\sigma_1 - \sigma_3) &= 2(C - \mu t)((1+\mu^2)^{1/2} + \mu) \qquad (5)\\ &= 4C - 3t \text{ for } \mu = 0.75\end{aligned}$$

Above this critical stress hydro-fracturing is impossible and only shear failure can occur. Accepting $C = 10$ bar, and taking the extreme case when $t \to 0$, the maximum differential stress allowing hydro-fracturing is just 40 bar. It will be correspondingly greater for intact rocks or a hydrothermally cemented fault, but in comparison with the differential stresses of several kilobars generally required to induce microcrack dilatancy[18], hydro-fracture dilatancy is clearly a low-stress phenomenon.

This critical stress condition may be considered in relation to Anderson's[19] three modes of faulting (based on whether the vertical stress $\sigma_v = \sigma_1$, σ_2, or σ_3), and the ratio of fluid to overburden pressure, $\lambda_v = P/\sigma_v = P/\rho g z$ (ρ being the average rock density, g the gravitational acceleration and z the depth). Previous studies[13,20] have shown that λ_v should be respectively greater and less than unity for hydro-fracturing in thrust and normal fault terrains, but have not taken full account of this limit to differential stress.

For thrust faults $\sigma_v = \rho g z = \sigma_3$, so from equation (4) the condition for hydro-fracturing is

$$\lambda_v = 1 + t/\rho g z \qquad (6)$$

requiring $\lambda_v \geqslant 1$ always. In the case of simultaneous hydro-fracturing and normal faulting, $\sigma_v' = \rho g z\ (1 - \lambda_v) = \sigma_1'$, so from equations (3) and (4),

$$\rho g z (1 - \lambda_v) = 2K^{\frac{1}{2}}C - Kt \qquad (7)$$

For simultaneous wrench faulting and hydro-fracturing, the particular situation where $\sigma_v' = \sigma_2' = \frac{1}{2}(\sigma_1' + \sigma_3')$ is considered. Then again from equations (3) and (4),

$$\rho g z (1 - \lambda_v) = K^{\frac{1}{2}}C - \tfrac{1}{2}t(K+1) \qquad (8)$$

Equations (6), (7) and (8) can be used to separate fields of potential shear failure and hydro-fracturing for the three faulting modes on plots of λ_v versus depth (Fig. 3). As an example, the delimiting curves have been drawn for the top 10 km of a crust with average density $\rho = 2.55$ g cm^{-3}, containing a fault–fracture system with failure parameters, $C = 50$ bar, $t = 10$ bar and $\mu = 0.75$. The barbed side of each curve represents the field of potential hydro-fracturing, except for the thrust regime where the curve marks conditions in which hydro-fracturing must occur. Note that the curve for wrench faulting is displaced towards those for normal and thrust faulting as the value of σ_2 moves respectively towards σ_1 and σ_3 from the median case considered.

Fluid pressures at least equivalent to the hydrostatic head ($\lambda_v = 0.39$ in this case) may generally be expected in established fault zones[15], so that in the uppermost regions of both normal and wrench faults, hydro-fracturing should inevitably accompany faulting. This may account for the extensive fissuring often observed in association with normal faults at the surface[21]. For hydro-fracturing at greater depths, fluid pressures must exceed

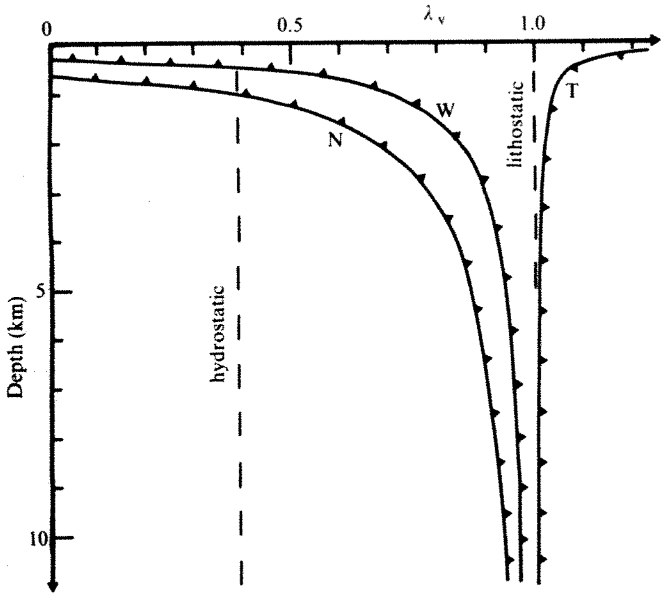

Fig. 3 Curves delimiting potential fields of shear failure and hydro-fracturing (barbed side) for the different faulting modes (T, thrust; W, wrench; N, normal). ($\rho = 2.55$ g cm^{-3}, $\mu = 0.75$, $C =$ 50 bar and $t = 10$ bar).

the hydrostatic head for all faulting modes. Such abnormal fluid pressures may arise through a variety of mechanisms but the presence of highly impermeable 'cap' layers is generally necessary[22]. However, throughout the frictional regime the required λ_v values remain significantly lower for normal faults than for thrusts, with those for wrench faults lying between. I have found that arrays of vertical extension veins around normal faults, as at Konarak, tend to be more common than subhorizontal veins associated with thrust faults. This contrasts directly with the common view[6] that dilatant effects should be more pronounced around thrust faults. Hydro-fracturing (particularly the opening of vertical extension fractures in normal and wrench fault terrains) may clearly also act as a regulatory mechanism, preventing fluid pressure from rising above the critical λ_v value for a given depth and faulting mode, once it exceeds the hydrostatic head.

The relationship between the onset of hydro-fracture dilatancy and the earthquake stress cycle is uncertain, and may vary with faulting mode. However, at Konarak there is evidence for the partial collapse of the dilatant vein array at failure in the form of clastic sandstone dykes which have been mobilized to cut across the gypsum extension veins before feeding onto the faults (Fig. 1). For pre-slip hydro-fracturing during stress accumulation at other than shallow depths around normal and wrench faults, fluid pressure must be sufficiently high for λ_v to exceed or attain the critical value for the particular depth, faulting mode and failure parameters (Fig. 3). Once hydro-fracturing has occurred, fluid pressures should drop towards the hydrostatic, resulting in an increase in effective normal stress and the strengthening of the fault. Shear failure then becomes possible once differential stress has risen sufficiently to overcome this dilatancy hardening effect.

I thank Dr B. K. Atkinson and Dr N. J. Price for helpful comments. Fieldwork at Konarak was accomplished during the 1976 Royal Geographical Society–Imperial College Expedition ot the Iranian Makran. I also thank the expedition members for assistance.

Reworking in Upper Mesozoic and Cenozoic central Pacific deep-sea sediments

Jörn Thiede

Department of Geology, University of Oslo, PO Box 1047,
Blindern, Oslo 3, Norway

Data from deep-sea drilling cores from upper Mesozoic and Cenozoic central Pacific Ocean sediments have been used to estimate the frequency with which pelagic microfossils in sediments of different ages include species which have been displaced from older deposits. Intruding microfossils, which include planktonic foraminifera and calcareous nannofossils, and to a minor degree also radiolarians and diatoms, are most easily distinguished by not being contemporaneous with the sediments in which they are found. Presumably their occurrence arises from the mechanical reworking of oceanic sediments by bottom water currents. The data suggest that there were pulses of intensive reworking around 40 Myr BP, 30 Myr BP, 15 Myr BP, 5–10 Myr BP and during the Plio–Pleistocene; these pulses were interrupted by phases of only modest erosion on the Pacific Ocean floor. The absence of reworking of non-contemporaneous fossils in sediments older than 70 Myr suggests relatively sluggish deep-sea currents which were not able to erode deeply into the underlying Cretaceous and in certain areas Jurassic sediments.

Descriptions[1] of sediment columns probed by the Deep-Sea Drilling Project (DSDP) in the central Pacific quite frequently mention the occurrence of non-contemporaneous (reworked) microfossils which are older than the deposits in which they are included. The sites of occurrence (Fig. 1) are distributed over the entire western subtropical and tropical Pacific Ocean, whose basaltic basement is dominantly of Jurassic, Cretaceous and early Tertiary age[2], but there are also sites from which reworked material has not been reported, either because none exists or because it has been overlooked. The collected data[1] come from 35 DSDP sites drilled during 13 legs and are considered representative. Sediments with reworked fossils span a wide range of time (from late Jurassic–early Cretaceous to Quaternary) and depth (>1.5–<6 km), and most of them are located on the Mesozoic part of the Pacific Plate (Fig. 1). The poor coring record during the early DSDP phases and long hiatuses imply that deep-sea basin sites in the central Pacific Ocean are under-represented in comparison with elevated areas (aseismic rises and ridges). Given the wide area coverage of drill locations there is no bias towards a single deep-sea basin or towards one very special depositional environment. Many of the sites discussed here have been drilled on submarine elevations which in late Mesozoic times were at very shallow water depths, but which subsequently subsided several kilometres. The fact that the displaced fossils have come from pelagic sediments and that most of them have come from a depth interval above the calcite

0028-0836/81/080667—04$01.00

compensation depth (CCD) suggest intermediate (roughly equivalent to bathyal) source regions at the flanks of such submarine highs.

The distribution of displaced pelagic fossils in the central Pacific is based on 207 observations of the four major planktonic microfossil groups (diatoms, radiolarians, coccoliths, foraminifera) whose grain size spectra range from silt to sand-size material. About 80% of the observations are from occurrences of reworked calcareous nannofossils and planktonic foraminifera. The data are therefore biased towards the depositional environments of calcareous oozes above the CCD and under the influence of intermediate[3], but not the deepest, water masses of the oceanic water column.

The biostratigraphic zonations derived from pelagic microfossils are well correlated with absolute chronologies[4-6]. The difference between the age of reworked (zone) fossils and the surrounding sediment can therefore often be determined very precisely. The age difference between the reworked material and the time of displacement (age of the present host sediment) ranges in general between zero (the reworking of contemporaneous or pene-contemporaneous deposits) and a maximum value which is determined by the difference in age of the oldest eroded sediments and the time of deposition of the reworked components. The most surprising feature of the distribution of reworked pelagic fossils in the central Pacific (Fig. 2) is the almost complete lack of redeposition in the Mesozoic. The earliest occurrences are in Maastrichtian sediments, but there are few observations until the late middle Eocene when a major episode of erosion into older deposits began at the depth of the intermediate water masses of the central Pacific. The planktonic forminiferal faunas and calcareous nannofossil floras of many sites bear therefore ample evidence of widespread reworking of Eocene to Cretaceous faunas and floras[7]. The past 40 Myr have been a time of constant reworking of deep-sea sediments (Fig. 2) with peaks of erosive events $\sim$40 Myr BP, 30–32 Myr BP, 14–15 Myr BP, 7–8 Myr BP and during the past 5 Myr. The modest number of observations during 10–13 Myr BP and in particular 15–25 Myr BP and 33–38 Myr BP indicate a temporary decrease of intensity of erosive processes. A characteristic for the central Pacific (Fig. 2) is that only coeval sediments have been reworked during most of the Mesozoic (only Cretaceous).

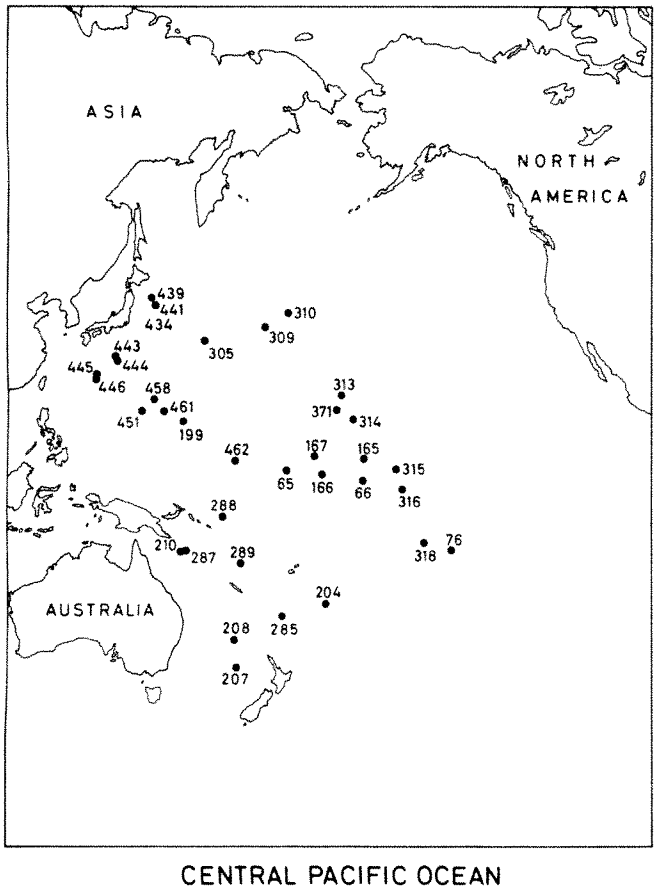

Fig. 1 Locations of deep-sea drilling sites with good coring records and reworked pelagic fossils in the tropical and subtropical central Pacific Ocean.

The time interval between the age of the eroded section and the time of final deposition of the reworked material can be large and the precision of this variable depends on the stratigraphic resolution[4-6]. The Mesozoic biostratigraphic zonations of deep-sea sediments are considerably less refined than Cenozoic ones[4]; thus Mesozoic and Cenozoic data from the central Pacific cannot be easily compared. However, the complete absence[1] of reworked non-contemporaneous pelagic microfossils in the pre-Maastrichtian parts of the central Pacific sediment section suggest that no older material has been subject to erosion in intermediate water depths during this time span. Age differences deviating considerably from zero only occur since Maastrichtian time (Fig. 2) when fossils from upper Campanian deposits were incorporated into chalks and calcareous oozes. The maximum age difference between the oldest reworked fossil components and the host sediment increased in a regular fashion from close to zero in Maastrichian to $\sim$38 Myr BP in late Eocene time when it reached 30–40 Myr. Between late Eocene and late Pliocene–early Pleistocene the maximum age difference fluctuated between 20 and 70 Myr. Maxima (Fig. 2) developed in the late Eocene, early Oligocene, early to middle Miocene and at the end of the Pliocene. Minima are confined to times when there are few observations of reworked pelagic material. The drastic decrease of the maximum difference in age of the reworked sediment components and the host sediment during early and late Pleistocene observed at Site 462 in the Nauru Basin[8] can also be seen in the data discussed here and seems to be a general feature of the redeposition of older pelagic deposits in the central Pacific.

Reworking and displacement of biogenic deep-sea sediment components imply mechanical erosion and transport of the fossil material[9] from an initial to the final site of deposition. Thus, the occurrence of reworked and displaced fossils in deep-sea sediments provides a simple tool for palaeoceanographic studies. Although reworked fossil material is abundant in certain horizons[10,11], it is generally only a minor fraction of the total sediment. Such fossils are therefore seldom described in detail in studies of the biostratigraphy and/or the depositional environment of Mesozoic and Cenozoic sedimentary sequences. The presence of reworked and displaced contemporaneous pelagic microfossils is often difficult to detect because of the apparently homogeneous nature of many deep-sea sediments and because displaced fossil assemblages cannot easily be discerned from autochthonous ones. The sedimentary structures in the modern ocean floor reflect intense bottom water current activity. The textural properties of deep-sea sediments[12] and sedimentary structures encountered in DSDP cores suggest that this also happened in the past, although it is difficult to evaluate the importance and the amount of reworked coeval material. The presence of displaced, non-contemporaneous pelagic sediment components is much easier to determine than that of contemporaneous material. They offer information about the nature, stratigraphy, palaeodepth of deposition and source of the eroded sediment section as well as about the current regimes of the depositional environments of the host sediment. Calcareous pelagic material has been eroded mostly from intermediate (deeper than neritic, but shallower than CCD) waters, purely siliceous displaced fossil assemblages from regions below the CCD.

The large difference between Mesozoic and Cenozoic redeposition (Fig. 2) of non-coeval reworked pelagic sediment components in the central Pacific is surprising. Maastrichtian events which reworked the directly underlying Campanian sediments represent the beginning of current regimes in the

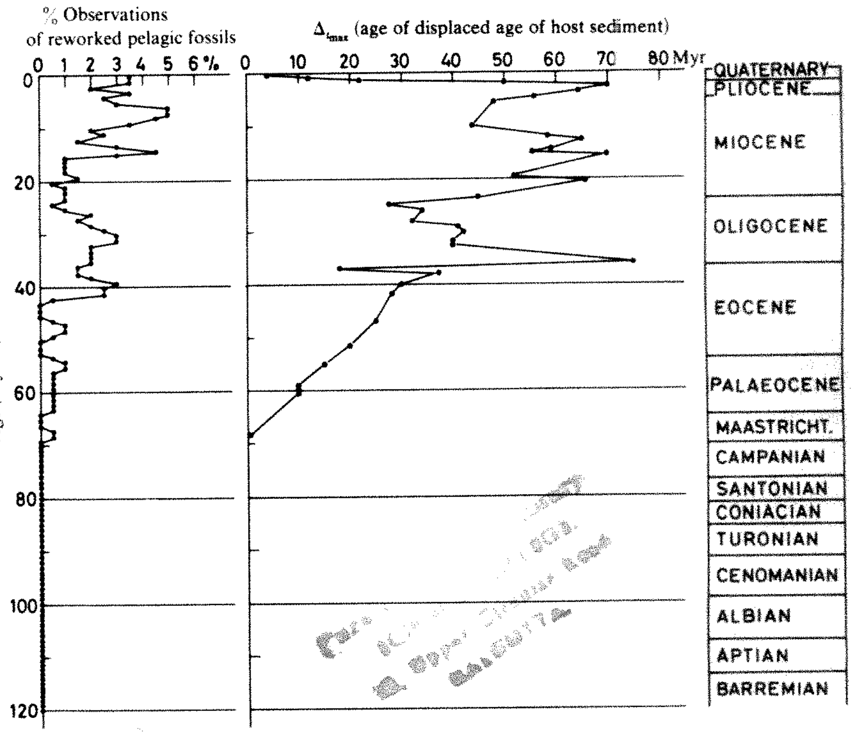

Fig. 2 Occurrence of non-contemporaneous reworked pelagic microfossils (calcareous nannofossils, planktonic foraminifers and radiolarians) in drill sites from the subtropical and tropical central Pacific Ocean (Fig. 1). Occurrence is expressed in per cent of total occurrences of reworked non-contemporaneous microfossils. $\Delta_{t_{\max}}$ is the maximum time difference per time interval between the age of the reworked and displaced pelagic fossils and of the host sediment.

intermediate water masses of an intensity which not only allowed transportation and displacement of coeval sediments, but also erosion of the underlying older strata. This is different from the South Atlantic palaeoenvironment where pelagic sediments as old as Coniacian have been displaced into deposits of Santonian age[13]. Although the available data are preliminary, the large quantitative differences of erosion and redeposition during pre-Maastrichtian and Maastrichtian–Pleistocene times indicate a fundamental change of the depositional palaeoenvironment of the deep central Pacific and probably of the world ocean in general. If the physical properties of deep-sea sediments[14] deposited during pre-Campanian time in the central Pacific were not drastically different from those laid down during the past 75 Myr, then their erosive potential should have been approximately the same. Moreover if diagenetic changes have affected the physical properties of the pre-Campanian then these diagenetic changes must have occurred soon after deposition of these sediments.

The lack of reworked pelagic microfossils older than their pre-Maastrichtian host sediments coincided with the repeated development of oxygen deficient depositional environments between 80 and 120 Myr BP. The very quiet and sluggish bottom water circulation which is suggested by the laminated sediments[15] of the anoxic lithologies supports the interpretation that a wide area of the pre-Campanian central Pacific in intermediate water depths has not experienced bottom water currents strong enough to erode older strata and to transport the resuspended sediment particles. Relatively rapidly flowing currents seem to have been confined to the upper few hundred metres of the water column, especially close to the equatorial divergence[15].

The number of occurrences of reworked non-coeval pelagic fossils (Fig. 2) remained modest from Maastrichtian to late middle Eocene times, but minor peaks during late Palaeocene and early middle Eocene represent short lived erosive events of a modest scale. The remainder of the Cenozoic was characterized by depositional palaeoenvironments where erosion in intermediate water depths was predominant. The temporal coincidence of important reworking with major changes of the oceanic bottom water temperature regimes (Fig. 3) as deduced from the δ^{18}O ratios of the benthic foraminifers[16,17], suggest that these episodes represent major changes in the bottom water current regimes due to the advection of cold polar probably Antarctic[8,19] to the intermediate waters in the central western Pacific Ocean. This advection resulted in more rapidly flowing currents which eroded the ocean floor and generated widespread hiatuses through reworking and mechanical redeposition of biogenic sediments rather than through dissolution. We do not know whether the pre-late middle Eocene reworking events can be explained by the formation of modest quantities of polar bottom waters much earlier than presumed hitherto which coincided with a significant temperature decrease in high latitudes in Maastrichtian times[20].

The time difference between age of reworked components and time of redeposition reflects the length of the stratigraphic column which was subject to erosion at the time of redeposition; it approached zero during Maastrichtian time, but increased fairly regularly throughout the Cenozoic to the early Pleistocene. The regular increase must mean that the entire sediment column which had been laid down since initiation of the deep

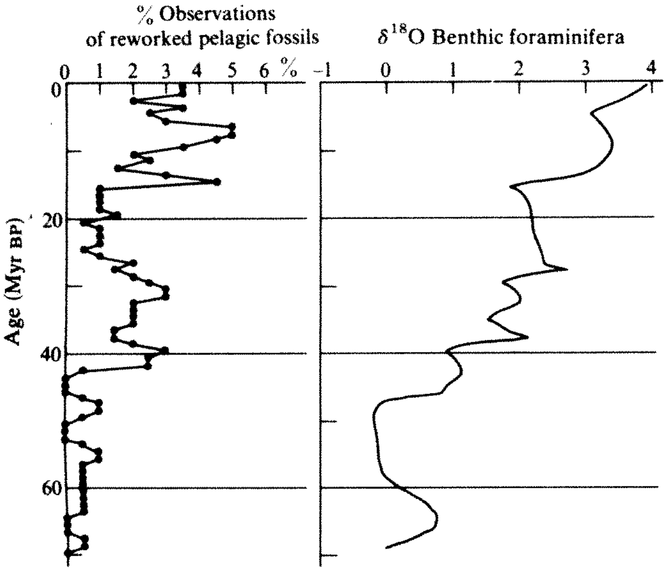

Fig. 3 Occurrence of non-contemporaneous reworked pelagic microfossils in the central Pacific Ocean and oxygen isotope ratios in benthic foraminifers through the past 70 Myr. Isotope data mostly from the North Pacific Ocean[17].

water current regime in the early Maastrichtian was subject to continuous erosion and redeposition. Deviations from the regular increase of the maximum time difference between the age of the reworked material and of the time of redeposition have been observed during early and late Oligocene as well as during late Miocene and Quaternary. Minima of age difference (Fig. 2) coincide with episodes of high pelagic accumulation rates[21,22], the maxima with the development of important hiatuses in the western Pacific Ocean[23]. The presence of reworked and displaced non-coeval fossils in deep-sea sediments implies mechanical transport and suggests that mechanical erosion rather than non-deposition or dissolution causes most of these hiatuses. The decrease of the maximum age difference between reworked and host sediments in the Central Pacific during the past 3–4 Myr suggests a reduction in the intensity of erosion in the intermediate part of the oceanic water column, despite the deteriorating climate. This is supported by accumulation rate data[24] from the polar South Pacific which indicate a decrease of erosion due to a decrease in current velocities over the past 3 Myr.

Changes of the global palaeoenvironment across the boundary from the late Mesozoic to the Cenozoic era caused: (1) an important decrease in the amount of hydrocarbons which formed on Earth[25]; (2) the initiation of a climatic regime which deteriorated from the equitable late Mesozoic mode to the Glacial mode towards the end of the Cenozoic; and (3) a catastrophy within the biosphere which led to the extinction of many forms of life on land and in the oceanic surface water masses. This development had previously been related to a gradual change of the global palaeoenvironment towards the end of the Cretaceous. More recently instantaneous events such as the sudden injection of brackish water masses from previously isolated Arctic Ocean[26] or the impact of a small celestial body[27] have been invoked to explain the sudden catastrophy at the Cretaceous–Tertiary boundary. However, the evidence from reworked pelagic fossils in the central Pacific Ocean indicates that an important component of the late Mesozoic palaeoenvironment, the current regimes of the intermediate and deep oceanic water masses, changed ~5 Myr earlier than the catastrophic events on land and in the pelagic surface waters of the oceans.

The data used in this report have been produced by the shipboard palaeontologists and sedimentologists of the DSDP Legs 7, 9, 17, 20, 21, 30, 32, 33, 57 to 61, their skilful work is acknowledged. We thank O. Eldholm (Oslo), and W. H. Berger for helpful comments. The Deep-Sea Drilling Project (DSDP) is operated by Scripps Institution of Oceanography with advice from the Joint Oceanographic Institutions.

Cenozoic palaeotemperature changes and planktonic foraminiferal speciation

Robert C. Thunell

Department of Geology and Belle W. Baruch Institute for Marine Biology and Coastal Research, University of South Carolina, Columbia, South Carolina 29208

The interaction of plate movements and progressive climatic deterioration produced a constantly changing oceanic environment during the Cenozoic. The destruction of the Tethyan Seaway and the severing of low-latitude oceanographic connections during the past 65 Myr (ref. 1), coupled with the initiation of unrestricted circum-Antarctic circulation in the middle to late Oligocene[2], provided the necessary boundary conditions for the development of a global ocean marked by steep latitudinal temperature gradients. This is in contrast to the rather mild climate of the Mesozoic, which was characterized by an ocean with a homogeneous thermal structure and weak latitudinal temperature gradients[1]. Throughout the Cenozoic, marine plankton were constantly adapting to major changes in the oceanic environment. This can be seen, for example, in the continual development of latitudinal provincialization as a response to polar coolings[1,3]. Here I attempt to evaluate the relationship between palaeotemperature change and planktonic foraminiferal speciation during the past 65 Myr.

Earlier studies compared patterns of planktonic foraminiferal evolution with available palaeotemperature data[4–8]. Frerichs[7] suggested that rapid radiation and high diversity of planktonic foraminifera coincided with periods of warm climate, whereas Cifelli[5] and Lipps[6] both concluded that planktonic foraminiferal diversity was closely regulated by high-latitude marine climates. According to their models, when latitudinal temperature gradients are enhanced there is increased provincialization, while periods with globally uniform oceans are marked by low diversity and wide geographical distribution of species. Stehli *et al.*[9] and Cifelli[5] also proposed that the rate of evolution of new taxa is highest in regions of warmest surface waters. If true, marine sequences from tropical–subtropical regions should be an excellent record of the major features of planktonic foraminiferal evolution. Hart[10] suggested that not only is foraminiferal evolution closely related to palaeotemperature changes, but that the interative trends[5,11] observed during the Cenozoic "indicate successive attempts at colonizing deeper levels of the winter column".

The present data are based on a synthesis of Palaeocene to Recent planktonic foraminiferal distributions in marine and land-based records from the Caribbean region[12]. This compilation is based primarily on the results of Legs 4 (ref. 13) and 15 (refs 14, 15) of the Deep Sea Drilling Project, as well as information from the Antilles and northern South America[16–18]. The past 65 Myr has been divided into 43 planktonic foraminiferal zones[14,15], varying in duration between ~0.5 and 3.4 Myr (ref. 19). For each of these zones species diversity and the number of first and last appearances have been determined (Fig. 1). The species diversity data enable the total rate of change of planktonic foraminifera to be estimated in terms of number of species per Myr (Fig. 1).

The $\delta^{18}O$ record used in this study is a compilation of previously published benthic foraminiferal data[20]. The Cenozoic $\delta^{18}O$ record reveals that there has been a persistent cooling of the oceans since the late Palaeocene. Superimposed on this trend are a series of distinct climatic and oceanographic events, including: (1) the development of the psychrosphere near the Eocene–Oligocene boundary[21]; (2) the establishment of an unrestricted circum-Antarctic current in the middle to late Oligocene[2]; (3) the development of a permanent Antarctic ice cap in the middle Miocene[22]; and (4) the onset of Northern Hemisphere glaciation in the late Pliocene[23–26].

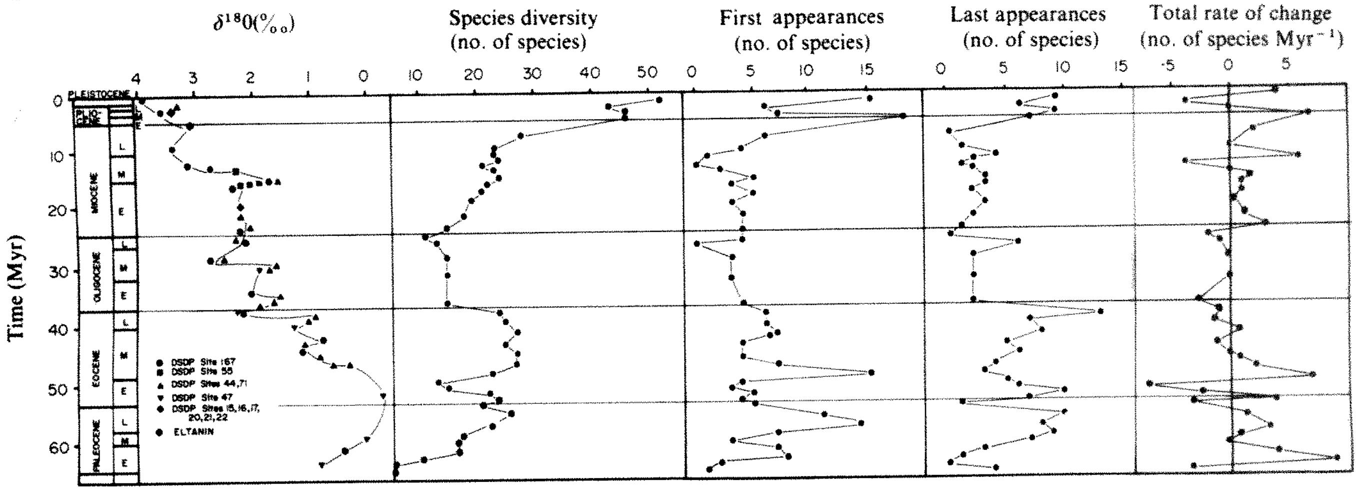

Fig. 1 Comparison of Cenozoic $\delta^{18}O$ record with various faunal parameters reflecting the diversity of planktonic foraminifera. The $\delta^{18}O$ curve is from ref. 20 and is a composite record based on analyses of benthic foraminifera from different deep-sea sedimentary sections. The faunal data base is from ref. 12. Geological epochs and an absolute time scale after Berggren[19] are plotted on the left.

The palaeotemperature record indicates that a gradual warming occurred throughout the Palaeocene. Associated with this warming is an increase in species diversity (from <5 species at the base of the Palaeocene to >25 species in the late Palaeocene), with the morphologically simple globigerine forms that survived the massive extinctions at the end of the Mesozoic giving rise to the more advanced globorotaliid forms[5,27]. There are two distinct episodes of rapid origination within the Palaeocene, one in the early and one in the late Palaeocene. These are reflected in the total rate of change of the fauna, with the Palaeocene generally being a time of net gain in overall number of species.

Following the diversity high in the late Palaeocene there was a rapid decrease in species number with a low being reached by the end of the early Eocene. There is a sharp decline in the number of first appearances during this time interval, while the number of last appearances remains relatively high. The result is a net loss in species with the latter part of the early Eocene being marked by the greatest decrease for the entire Cenozoic. This is when the long-term cooling trend for the Cenozoic probably began, although there is no abrupt change in the isotopic record with which we can specifically correlate the observed faunal events.

A second major increase in species diversity occurred in the Palaeogene, extending from the middle Eocene through the end of the Eocene, where first appearances exceed extinctions. The major evolutionary feature during this period was the introduction of hastigerine, orbuline and truncorotaliid forms[5,27]. The palaeotemperature record indicates a brief warming during the middle Eocene followed by relatively stable climatic conditions throughout the remainder of the Eocene. (A similar pattern is shown by isotopic work reported in refs 22, 28, 29.)

One of the most dramatic events in the Tertiary oxygen isotopic record is associated with the Eocene–Oligocene boundary (~38 Myr ago). This rapid isotopic change has been attributed to a cooling of Antarctic waters and the development of cold bottom water circulation (psychrosphere) similar to that of the present day[21]. The response of planktonic foraminifera to this new oceanographic regime is manifested as a sudden drop in species diversity, (from ~25 to 15 species) with the largest number of last appearances for the entire Cenozoic. By the end of the Eocene, all globorotaliid, hastigerine, orbuline and truncorotaliid forms had become extinct. As at the Cretaceous–Tertiary boundary, the simple globigerine forms were among the few survivors of the Eocene–Oligocene event. A similar crisis in benthic foraminifera was reported by Kennett and Shackleton[21], although Corliss[30] suggests that the benthic turnover may have occurred in more gradual steps.

Following the climatic deterioration at the Eocene–Oligocene boundary, fairly stable oceanographic conditions were maintained until the middle Oligocene. This stability is reflected in a planktonic foraminiferal fauna with uniformly low diversity. The simple globigerine assemblage present at this time has a global geographical distribution indicating the absence of any strong latitudinal thermal barriers.

Another abrupt isotopic shift occurs in the middle Oligocene. This isotopic event coincides with the initiation of unrestricted circum-Antarctic flow[2], and may reflect a high-latitude cooling. This isotopic event coincided with the largest eustatic drop in sea level of the entire Cenozoic[31]. Each faunal parameter suggests that there was a delay in the response of planktonic formaminifera to this oceanographic event. Shortly after the isotopic shift, planktonic foraminiferal species diversity reached a low point, the number of first appearances dropped to zero, and there was an increase in last appearances. This offset in the isotopic and faunal records may reflect a lag in the response of planktonic foraminifera to changing surface conditions, or it may be a stratigraphic artefact. The ubiquitous globigerine forms continue to dominate the planktonic foraminiferal fauna of the middle and late Oligocene.

This diversity low in the late Oligocene is followed by a very uniform increase in the number of planktonic foraminiferal species that begins in the early Miocene and continues throughout the remainder of the Neogene. Species diversity increases from ~10 species in the late Oligocene to 25 species by the end of the early Miocene. Cifelli[5] considered this to be one of two major expansions in planktonic foraminifera that occurred during the Cenozoic (the other following the massive extinctions at the Cretaceous–Tertiary boundary), with the modern fauna beginning to evolve at this time. Phylogentically different lineages of globigerinoids, globorotaliids, hastigerines and orbulines reappeared during the early Miocene. The palaeotemperature record indicates a slight warming at the end of the Oligocene, followed by stable conditions during the early Miocene. Associated with these uniformly warm conditions of the early Miocene were a constant rate of first appearances and a low level of last appearances resulting in net gain in total fauna.

The relatively stable oceanographic conditions of the early Miocene ended abruptly in the middle Miocene (about 14–12 Myr ago) with the development of a permanent Antarctic ice cap[22]. This major climatic event is manifested by the largest isotopic shift in the Cenozoic record, and further enhanced latitudinal provincialization of all planktonic microfossil groups[3]. First appearances drop to zero, while the number of extinctions increases slightly in the middle Miocene producing a brief but relatively large net loss in species. Throughout this period species diversity remains fairly stable, fluctuating between 21 and 24 species.

The most rapid increase in species diversity during the past 65 Myr occurred in the early Pliocene. Within several million years, the number of planktonic foraminiferal species increased from <30 in the late Miocene to >45 in the early Pliocene. Since the middle Miocene, the world had been in a glacial state but the isotope record indicates that a slight retreat of the Antarctic ice cap may have occurred in the early Pliocene. The rapid increase of planktonic foraminifera at this time may have been a response to this brief amelioration.

The most recent major climatic threshold was the initiation of Northern Hemisphere glaciation in the late Pliocene (~3.0 Myr ago)[23-26]. This probably intensified existing latitudinal temperature gradients. This climatic change immediately caused a dramatic drop in number of first appearances, a slight decline in species diversity and a short-term net loss in species.

Since the inception of the northern ice sheets, there have been periodic oscillations between glacial and interglacial climates. However, these rapidly changing climatic conditions have had very little adverse effect on planktonic foraminifera. The general pattern has been for the geographic ranges of individual species to expand and contract in response to changes in latitudinal temperature gradients, without any appreciable loss of species. Once planktonic foraminifera became adapted to the effects of a Northern Hemisphere ice sheet, species diversity increased and reached a maximum for the entire Cenozoic (>50 species).

This comparison of the Cenozoic palaeotemperature record and species diversity in planktonic foraminifera confirms the previously reported[4,7,8] close relationship between palaeoclimatic change and planktonic foraminiferal evolution. During the past 65 Myr, there have been five periods during which there was a net loss of the total planktonic foraminiferal population. These periods of net loss correspond closely to the major climatic events of the Cenozoic, and include the initial phase of climatic deterioration in the early Eocene, the development of the psycosphere near the Eocene–Oligocene boundary, the initiation of unrestricted circum-Antarctic flow in the middle to late Oligocene, the build-up of a permanent Antarctic ice cap in the middle Miocene and the onset of Northern Hemisphere glaciation in the late Pliocene. Following each of these major climatic events there was generally an expansion of planktonic forminifera associated with milder climate. The species diversity record clearly shows that there were two major radiations during the Cenozoic, one beginning in the early Palaeocene and one beginning in the early Miocene[5].

I thank Drs W. A. Berggren, B. H. Corliss and J. P. Kennett for helpful comments. This work was partially supported by NSF grant OCE79-23736 and a Research and Productive Scholarship Grant from the University of South Carolina.

Rates of emission of H_2S from plants and patterns of stable sulphur isotope fractionation

W. E. Winner*, C. L. Smith*, G. W. Koch*, H. A. Mooney*, J. D. Bewley† & H. R. Krouse‡

* Department of Biological Sciences, Stanford University, Stanford, California 94305
† Department of Biology and ‡Department of Physics, University of Calgary, Calgary, Alberta, Canada T2N 1N4

In all green plants both HSO_3^- and SO_4^{2-} are reduced during photosynthesis, and many species can emit the product as H_2S gas. Plants will emit H_2S after fumigation with acute doses of SO_2 gas[1,2], irrigation with 5% K_2SO_4 solutions[3], or immersion of roots in HSO_3^- and SO_4^{2-} solutions[4]. If such emissions of H_2S by plants occur in nature, then this process adds sulphur to the atmosphere and contributes to the global sulphur budget. Oxidation of biogenic H_2S in the atmosphere may also contribute to the formation of acid rain. We report here that irradiated plants with roots immersed in HSO_3^- and SO_4^{2-} solutions at concentrations found in nature emit H_2S from their leaves, and that the fractionation of stable isotopes of sulphur during H_2S emission may be useful for identifying atmospheric sulphur that has been generated by photosynthetic reduction of sulphur.

Rates of emission of H_2S were measured for 10-week-old soybean plants (*Glycine max* L. Merr. cvs. Kent, Peking and York) raised in growth cabinets. Days were 12 h long, photosynthetically active radiation (PAR) was about 600 μE m^{-2} s^{-1}, humidity was 50–60% and the temperature was 15 °C at night and 20 °C during the day. Plants were prepared for experiments by removing them from potting media, washing and trimming their roots, and placing them in a flask with distilled water. The flask and plants were placed in a flow-through Plexiglass chamber, the upper portion of which was isolated by a diaphragm. Free space around the canopy was reduced by foam spacers inserted into the chamber, and air around the leaves was mixed by a propeller, driven by an electrical motor mounted outside the chamber. The roots were aerated by one airstream, and another airstream was passed through activated charcoal and used to flush the air space around the leaves. The chamber wall, diaphragm, foam spacers and propeller were lined with FEP Teflon to reduce H_2S absorption. After 30 min of incubation, the chamber was sealed, and air leaving it was analysed for H_2S with an Interscan Model 1170 sp H_2S analyser. Sampling was limited to 15 min to prevent water vapour from condensing in the chamber. Radiation by Sylvania Cool Lux bulbs was filtered through water and was 500 μE m^{-2} s^{-1} (300–760 nM) inside the chamber.

Plants in distilled water were tested for H_2S emission, then Na_2SO_4 (Baker, analytical grade) was added to the flask to increase the amounts of SO_4^{2-} available to the roots. Concentrations of SO_4^{2-} in the test solutions were 0.04, 0.1 and 1.0 mM. The highest concentration used is thought to be optimal for growth of agricultural crops[5], and the lowest concentration is similar to that of acid rain in the eastern US[6]. After treatment with the series of SO_4^{2-} solutions, plants were dried in an oven and rates of H_2S emission calculated on a plant dry-weight basis using the formula:

$$J_{H_2S} = XFW^{-1} \qquad (1)$$

where J_{H_2S} is the H_2S emission rate (ng g^{-1} s^{-1}), X the H_2S concentration leaving the chamber (ng cm^{-3}), F the airstream flow rate (cm^3 s^{-1}) and W plant dry weight (g).

0028-0836/81/080672—02$01.00

A similar system was used to determine the fractionation of stable sulphur isotopes during emission. We used 4-week-old cucumber plants (*Cucumis sativus* L. cv. Straight Eight) grown in a greenhouse, because these were found to emit H_2S in previous experiments[4]. The isotopic composition of the test solutions (0.1–0.2 M HSO_3^- or SO_4^{2-}) was known. To obtain sufficient H_2S for analysis with a mass spectrometer, sulphur ions were at a higher concentration in test solutions for these experiments than for determining rates of emission. The H_2S emitted by the plants was trapped as Ag_2S by filtering the air leaving the chamber through $AgNO_3$ deposited on quartz wool. This procedure was repeated several times with fresh plants and fresh test solution until several mg of Ag_2S were collected. The H_2S traps showed no selectivity for sulphur isotopes. After these experiments, leaves were oven dried, and sulphur was combusted to SO_4^{2-} in a Parr bomb. Washings were treated with Ba^{2+} to precipitate $BaSO_4$ and then chemically reduced to yield Ag_2S[7]. $\delta^{34}S$ values (Table 1) for Ag_2S from both leaf sulphur and H_2S gas were determined by isotope ratio mass spectrometry by reacting Ag_2S with Cu_2O at 900 °C, to form SO_2.

H_2S was detected from plants in all test solutions containing SO_4^{2-} (Fig. 1). Even plants in the most dilute solutions (0.04 mM) had a mean emission rate of 0.036 ng g^{-1} s^{-1}. Rates of emission increased as the concentration of SO_4^{2-} in the test solution increased, and the highest rate recorded was 0.07 ng g^{-1} s^{-1} for plants treated with a test solution of 1.0 mM SO_4^{2-}. H_2S emission rates persisted for several hours when experiments were prolonged. Emission rates observed here are lower than the 10 μg g^{-1} s^{-1} observed for detached cucumber leaves treated with 25–100 mM SO_4^{2-} and higher than the 0.6 pg g^{-1} s^{-1} observed for spruce seedlings[3]. When the lights were turned off after two experiments, emission rates declined within 15 min to about 30% of the highest rate. Other workers have also observed the light dependence of SO_4^{2-} reduction[8,9] and H_2S emission[1,2,4]. No H_2S was emitted from plants placed in distilled water, and there seemed to be no consistent differences in emission rate between the three cultivars at any single concentration of SO_4^{2-}.

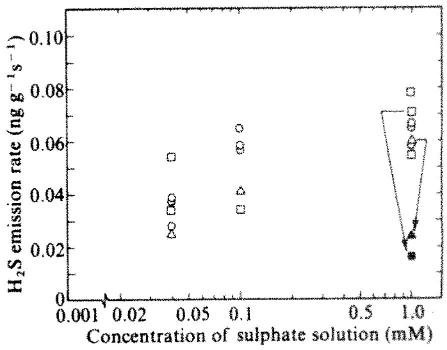

Fig. 1 H_2S emission rates (plant dry-weight basis) from irradiated soybean plants (open symbols) and from two plants transferred to darkness for a period of 15 min (closed symbols). Emission rates were monitored for three cultivars: ○, Kent; □, York; △, Peking.

If SO_4^{2-} is available to plants at a concentration of 0.05 mM and they emit H_2S at a rate of 0.04 ng g^{-1} s^{-1}, then the amount of H_2S produced worldwide from photosynthetic reduction of SO_4^{2-} could be 5.4×10^{13} g yr^{-1}. This constitutes about 50% of the amount needed to balance the global sulphur budget[10,11]. Our calculations were made by estimating global biomass at 1.85×10^{12} dry tons[12], by assuming that about 5% of this weight is composed of leaves[13], and then by averaging the daily photoperiod to 12 h. Plants may emit H_2S at greater rates if SO_4^{2-} concentrations are generally greater than 0.05 mM. In addition, H_2S emitted by plants may be oxidized in the atmosphere and eventually returned to soils in the form of acid rain. A single sulphur atom could conceivably be cycled many times between the soil and atmosphere by the processes of H_2S emission from plants and acid rain.

H_2S emitted by plants contained more ^{32}S and less ^{34}S than either the leaves or the test solutions (Table 1). δ^{34} S values differed by −9.7‰ from the SO_4^{2-} source and ~ −16.8‰ from the HSO_3^- source. The more extreme isotope fractionation pattern observed for HSO_3^- was also observed when both oxidized sulphur ions were supplied to plants in one solution. These results suggest that when both HSO_3^- and SO_4^{2-} are available, the emitted H_2S originates from the HSO_3^- source.

Photosynthetic sulphur-reducing bacteria show similar ^{32}S selectivity during H_2S formation[14]. Thus, depletion of ^{34}S resulting from isotope fractionation during H_2S formation may be common to chloroplasts and some prokaryotes. The ratio of isotopic rate constants for S–O bond rupture during inorganic reduction is similar ($k_{32}/k_{34} = 1.022$)[15] to the fractionations seen in our experiments.

We suggest that stable sulphur isotope analysis may indicate whether or not atmospheric sulphur compounds have originated from vegetation. Atmospherics derived from H_2S emissions from plants should be enriched in ^{32}S compared with stable sulphur isotopes that are available to plant roots. These fractionation patterns are independent of the oxidation state of sulphur in the air. We have observed that the $\delta^{34}S$ values of plants reflect $\delta^{34}S$ values of sulphur in their environment[16–18], and we suggest that plants that emit H_2S should become enriched in ^{34}S relative to their sulphur source.

The stability of real ecosystems

P. Yodzis

Department of Zoology, University of Guelph, Guelph, Ontario, Canada N1G 2W1

Most current theoretical work on whole ecological communities is based on a conception of community dynamics (see, for example, refs 1, 2) in which the community resides in a neighbourhood of equilibrium. However, there is very little evidence that this is a realistic viewpoint. To test this fundamental assumption 'empirically', I have constructed here plausible community matrices[1,2] corresponding to 40 real food webs[3] and studied their local stability properties. I find that stability (in the sense of tending to return to the presumed equilibrium after a small perturbation) is far more likely if the interaction strengths are chosen in accord with the nature of the particular organisms in each food web, rather than strictly at random. Either this is a monumental coincidence, or the equilibrium viewpoint really is appropriate for quite a few real communities. Additional results of this analysis are that stability generally requires a degree of intraspecific interference on the part of some consumer species, whereas interspecific interference tends to exert a destabilizing influence.

As emphasized by Pimm and Lawton[4], element A_{ij} of the community matrix gives the *per capita* effect of species j on species i in a neighbourhood of the presumed equilibrium. This is an important observation, for it enables one to make plausible guesses about the relative strengths of some interactions. Thus, the *per capita* effect of an insect population on a tree population is much smaller than the *per capita* effect of trees on insects, and so on[4]. An additional advantage of this approach is that it treats the community matrix as a truly local object, which in reality it is. Thus, the results reported here are completely independent of any assumptions about global dynamics; in particular, these are not Lotka–Volterra models.

For any real food web, we can construct a plausible community matrix by specifying four real, positive parameters f_1, s_1, f_2, s_2, with f_1 and f_2 chosen from the interval $[0, 1]$, and applying the following rules (which also serve to define the parameters f_1, s_1, f_2, s_2): (1) Trophic interactions. These matrix elements are chosen as by Pimm and Lawton[4] when their discussion applies. Cases not covered by Pimm and Lawton are treated in the spirit of their approach. It is in this step that a pattern of interaction strengths is arrived at which expresses the nature of the particular organisms in the food web. (2) Intraspecific interference. If species i is a primary producer, matrix element A_{ii} is chosen at random from the interval $(-s_1, 0)$. In addition, a fraction f_1 of the consumer species, chosen at random, is given diagonal matrix elements chosen at random from the interval $(-s_1, 0)$. The diagonal matrix elements for all other consumer species are set equal to zero. (3) Interspecific interference. If two consumers i and j have a prey species in common, then these species may indulge in interspecific interference, and I will call the ordered pair (i, j) 'potential competitors'. (Interspecific interference can also arise from other causes, such as competition for nest sites, but I will neglect such interactions here.) For a fraction f_2 of the potential competitors, chosen at random, the corresponding matrix elements A_{ij} are decreased from the values assigned in step (1) by amounts chosen at random from the interval $(0, s_2)$.

The food webs used in this study are the 40 webs recently compiled from the published literature by Briand[3], which is the most thorough existing community food web collection. For a variety of parameter sets $\{f_1, s_1, f_2, s_2\}$, 100 plausible community matrices were constructed for each Briand food web, using the above rules and a pseudorandom number generator, and the fraction of stable community matrices corresponding to each food web was computed. The results of some of these computations are displayed in Tables 1–4.

Table 1 shows the effect of increasing the strength s_1 of the intraspecific interference (relative to, of course, the strength of trophic interactions). In these computations, $f_1 = 1$ (all species in the community experience intraspecific interference) and $f_2 = 0$ (there is no interspecific interference). It is readily seen that stronger intraspecific interference favours stability, just as one expects.

Table 2 shows the effect of increasing the fraction f_1 of consumer species which engage in intraspecific interference. In these computations $f_2 = 0$ again, and $s_1 = 10^6$. Because of this large value for s_1 and in view of Tables 1 and 3, the values given in Table 2 can be viewed as upper bounds on the fraction of stable systems. It appears that at least one-tenth and perhaps as much as one-half of the consumer species in these communities need to exhibit some degree of intraspecific interference if the equilibrium viewpoint is to apply.

Pimm and Lawton[4] use the term 'self-limitation' for what I am calling intraspecific interference (namely, negative A_{ii}), and they

argue[5] that it rarely occurs for consumer species. They seem to feel that negative A_{ii} means that intraspecific interference is not only present, but is furthermore the 'limiting factor' in the sense of Liebig. But surely any intraspecific interference, whether it is 'limiting' or not, will manifest itself in the community matrix as negative A_{ii}. For this reason I have avoided Pimm and Lawton's terminology, and feel that negative A_{ii} can be expected to occur quite often for consumer species.

The effect of interspecific interference is investigated in Table 3, with the parameter values $f_1=1$, $s_1=1$, $s_2=0.1$ fixed, while f_2, the fraction of potential competitors which participate in interspecific interference, varies. It can be seen that these interactions usually exert a destabilizing influence.

Finally, Table 4 explores the plausibility of the equilibrium viewpoint itself. The first column of this table gives the fraction of stable community matrices, constructed as above with $\{f_1, s_1, f_2, s_2\}=\{1, 1, 0, 0\}$. The second column was obtained as follows: after constructing each community matrix as above, all the positive and all the negative off-diagonal entries were randomly permuted, and then stability was checked. Thus, all predator–prey relationships were preserved, as was the average interaction strength in each matrix, but the detailed pattern of interaction strengths suggested by the particular organisms in each food web (step (1) above) was destroyed. Clearly, local stability was destroyed along with this pattern.

The third column in Table 4 results from a somewhat weaker disruption of the pattern of interaction strengths. In this case, for each community matrix constructed according to the original rules, the pairs of non-zero elements (A_{ij}, A_{ji}) were randomly permuted. Again, local stability is destroyed.

If the equilibrium viewpoint is not appropriate for these communities, there is no reason for local stability of the community matrix to be associated with a more plausible pattern of interaction strengths.

Other evidence in favour of the equilibrium viewpoint, though in a somewhat different conceptual framework from that embodied by ref. 1, has come from some simulation studies[6]. In a study which is closely related to the present one in spirit (published shortly after the submission of this paper), Lawlor[7] has found, for 11 avian and 10 reptilian competitive guilds, that

randomizations of community matrices constructed from measured resource overlaps often have a deleterious effect on stability. Although this result is suggestive, its bearing, like that of single-species studies[8], on the stability and dynamics of whole communities is not entirely clear.

Auerbach[9], applying Pimm and Lawton's community matrix rules to certain host-parasitoid systems, did not find any stable matrices. This is surely due in large part to the fact that he did not extend Pimm and Lawton's rules, as I have, to allow for varying degrees of intra- and interspecific interference. As pointed out by several authors[10-12], and reinforced by Tables 1 and 2, community matrix stability depends crucially on the extent of intraspecific interference (both in commonness of occurrence and in strength).

It has long been known that solutions to systems of autonomous ordinary differential equations can behave very strangely ('recurrent trajectories')[13,14]. More recently, the realization has grown that even very simple systems can exhibit very complicated dynamical behaviour ('chaos')[15,16]. For ecosystems, biology provides additional complications, such as seasonality, spatial migration, invasion, local extinction, fluctuating extrinsic factors, catastrophic extrinsic factors and phenotypic plasticity. In the face of all these complications, the equilibrium viewpoint is hardly to be taken for granted.

The above findings in favour of the equilibrium viewpoint legitimize a large body of ecological theory and suggest that it is worth pursuing this viewpoint further. At the same time, we should be aware of the many factors, both mathematical and biological, which complicate the picture, and strive to incorporate them into our ecological world-view.

I thank Frédéric Briand for providing me with his collection of food webs in advance of publication, and for some most interesting discussions. I also thank the University of Guelph for the provision of a substantial amount of computer time under its Special Computing Program.

Perception of sign language from an array of 27 moving spots

Vivien C. Tartter* & Kenneth C. Knowlton

Bell Laboratories, 600 Mountain Avenue, Murray Hill,

Many deaf people in the USA communicate in American sign language (ASL), which has an expressive capacity equivalent to that of a spoken language, although structurally independent of spoken languages[1,2]. It comprises hand and arm movements often combined with particular facial gestures; together these are sufficiently precise to transmit all the complexities and innuendoes of a language. Here we demonstrate that fluent ASL users can communicate easily when all they see of each other is an array of 27 light spots strategically placed on the hands and face. The results indicate the salient locations in normal sign perception, and suggest that it is feasible to transmit signs using the bandwidth of one telephone line rather than a much more expensive TV line.

In normal conditions, the understanding of sign language requires seeing the area in front of the signer's body from the top of the head to waist level, and within a few inches of each side—signs produced within a 6-inch radius of the chin are most precisely articulated[3]. Signs are differentiated from one another by hand shape (for example, index finger compared with little finger raised), hand orientation (for example, palm exposed rather than back of the hand exposed), type of movement (for example, movement towards compared with movement away from the signer), and 'place of articulation' (for example, a touch on the chin compared with a touch on the lips)[4,5]. Battison[5] estimated that there are 45 distinct hand shapes, 10 hand orientations, 10 movements and 25 locations—this indicates the precision required to distinguish signs. In addition it has been

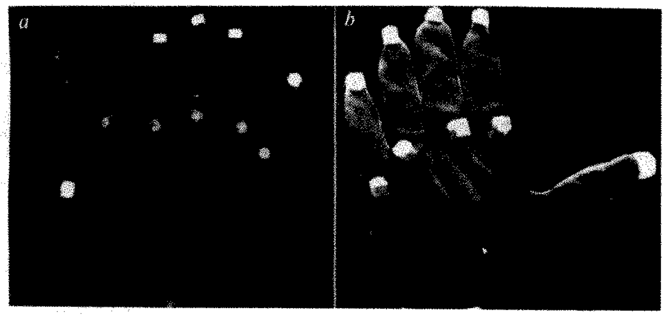

Fig. 1 A display of the back of a glove in *a*, lighting conditions in which only the reflections from the tape are visible and *b*, in normal lighting conditions.

suggested that facial expression may transmit critical information, perhaps redundantly[5], and that head movements may be critical for differentiating affirmatives, negatives and interrogatives[6].

To determine which information is critical for evoking the perception of the various features, we adapted the method of Johansson *et al.*[7,8] to study grosser types of biological motion. Johansson attached patches of retroreflective tape to the principal joints of subjects—wrist, elbow, shoulder, ankle, knee and hip—then filmed them moving in special lighting conditions so that only the patches of tape were visible. The two-dimensional display of light spots produced was clearly and immediately identified by observers as human motion: a person walking, running, cycling, and such. Presentation of a still picture alone from the display resulted in perception of lights—the motion was necessary to convey the structural relation between the lights and thus to evoke perception of human action.

As signing comprises human movement, although faster, more finely detailed, and less repetitive than that studied by Johansson, it seemed possible that the same perceptual mechanisms which organized the spots of light in Johansson's displays into meaningful patterns could organize strategically placed light spots on the hands into hand shapes and motions. The problem was to derive a configuration of spots which would convey each of the important feature values in sign without confusion, and which would be immediately perceived as moving hands, suggesting that these points are normally the salient ones for sign perception. (Note that Poizner *et al.*[9] used a similar technique to code the motion patterns used for various inflections in ASL. For this purpose one light on the index fingertip and reference points are sufficient to distinguish between 50 movement types.)

We devised a glove with 13 strategically placed pieces of tape, the largest and brightest at the regions which convey most information: a large piece on the thumb tip and slightly smaller ones on each of the remaining fingertips. On the back of the hand there was a smaller spot on each finger, just proximal to the second joint from the tip and there were four even smaller spots around the wrist. The backs of two gloves are shown in Fig. 1 in lighting which shows only the retroreflective tape spots (*a*), and in normal lighting (*b*).

With the palm of the hand forward, an outline of the hand is perceived (from the fingertips and wrist boundary). There is no hand shape which can be assumed with the palm forward in which the fingertips are not visible—closing of the hand is evident from the motion and the approach of the tip spots towards the wrist. Elevation of individual fingers is clear from the position of the raised fingers relative to the folded ones.

The back of the hand appears as fingertips followed by two more rows of spots. The row at the joints is necessary because with the back of the hand forward it is possible to curve the fingers so that the tips are not visible, as in a fist. In this case, curvature of the fingers is apparent as a disappearance of the fingertip spots, but information on hand shape is still preserved by the relative positions of the joint spots.

Information about hand orientation is given again by motion and the configuration of spots. Each spot is actually a spherical protrusion which is therefore uniformly visible from a wide range of viewing angles. Motion information is readily apparent in horizontal and vertical directions, as it was for subjects used in other studies[8,9], from the changes in position of the spots. Motion in depth is conveyed by a change in the size and spacing of the spots due to foreshortening.

To convey place of articulation only one additional reference point was necessary—a spot on the nose. A touch at the eyebrows is seen as a hand motion above the middle of the face; at the shoulders, as outside and below the middle of the face. No further reference points on the body were necessary, perhaps because of the grosser articulation outside the face area. The spot on the nose, in addition to providing a reference point, also gave information on head movements (nodding, shaking and

	How is your work?
[confused, so shadows what saw] How is . . .	
	How is your work?
[now understands] OK, OK.	
	Same, same. Boring
Same, same. OK	
	Thinking new job, I mean transfer to another job? Still waiting for another job? You. You!
For you? me. Thinking about transferring to another job maybe.	
	Same place or other place?
Same. Here. But change job.	
	For how long have you been waiting?
No. No. No. Been thinking for a pretty long time to get transferred so I have to wait for my supervisor to help me get another job.	
	Are you going to night school this fall?
I'm thinking of writing to Middlesex County College for night college but I have to wait for the reply. Still waiting for a man who is responsible for picking the deaf people to put into one class. People.	
	It seems to me that you have been thinking for a very long time. You'd better stop thinking and do it now, before it becomes too late. OK? [Pauses with no response] Do you understand me?
Yes. Talk. That I'm not worried about it.	
	Noooo . . ! You have been concerned for a *long* time. Concerned. Not important to think. Do it before it becomes too late.
Oh. I understand. You mean that if I . . .	
	You wait too long. No don't. Waiting is not that good.
I understand.	
Today it's very hard to get into college. Very difficult. Because too many people want enrolment.	No. No.
	No. Do you know what law number 504 means to you? Always assume that it's not hard to get in because you are deaf. No. Enrol (any) time you want. 504 guarantees enrolment.
[S gives feedback] Yes. Yes. I get it. I understand.	
But how can I get in? I mean I have to get permission from someone to get in.	
	Get. You want to get into college you have to go to admissions office and ask what courses you want; then he will put down (what) you ask him. You pay an interpreter, you pay for, and if college says no, you bring 504 law and show them, and if college won't believe you go to a court and ask for some -- [interrupts herself and restarts immediately with] because I learned from my friend who refused - (I mean) college refused to pay nothing so she went to court and the lawyer went to the college and college realized their mistake and they will pay for all interpreters. (It's) easy. You don't have to pay nothing.
Oh. I understand.	[Pauses briefly, then teases with] Chicken, chicken.

Fig. 2 One conversation of 4 min transcribed into English from videotaped record. Subjects at this point had 10 min experience with the system. Average signing rate was ~80 signs per min. S_1, S_2, subjects 1 and 2 respectively.

leaning forward), and provided feedback information to the person signing that the viewer was still watching.

Preliminary tests showed that effective communication at near normal rates is possible when viewing only the 27 points of light. Two pairs of deaf subjects were able to converse when viewing only the other's spots. Three of the four subjects were profoundly deaf, with hearing losses of 90 dB in the better ear. The fourth subject (C.F.) had some hearing and quite good speech. She and her partner were well educated with good reading and writing skills. Both learned ASL when young, and sign either ASL or English. The other two subjects had poor reading and writing skills and were only able to sign ASL. The transcript shown in Fig. 2 is an extract from the conversation of the first pair, translated into 'English' by C.F.

Each member of the pair was seated in a private room ~3 feet from a 21-inch TV monitor and a camera. The gloves and nose spot were placed on the subject, who was allowed a few minutes of self-viewing in normal lighting conditions. Then all the lights in each room except the one next to the TV camera were turned out, and the brightness and contrast of the TV monitors adjusted so that each subject could see only the spots. (Note that the camera was set so that movement within the signing space would be visible; thus the screen image of the spots was smaller than that displayed in Fig. 1. In addition, with movement, the spots commonly smear, leaving a slightly blurred image on each frame.) After self-viewing, the equipment was reconnected so that the subjects could see each other. They were instructed to discuss anything they wished and a free-flowing 20-min conversation ensued. Various topics were discussed by both pairs, with difficulties and requests for repetition only in finger spelling. A transcription of a portion of one pair's discussion is shown in Fig. 2. During this displayed segment the participants became quite heated—emotion was conveyed by the slow and abrupt movements of the spots. Nonmeaningful movements (for example, tugging at the gloves) were occasionally mimicked playfully, but no attempt was made to interpret them. Note that during debriefing both pairs of subjects reported that they really needed to concentrate, but that their conversation and understanding were normal except for finger spelling. Furthermore, all four subjects expressed their enjoyment of the system.

We believe that the picture that these subjects used could be coded to the capacity of one telephone line. This assumes that the useful information in each spot is its brightness or size, and position on the screen in time. A more controlled test is planned, using computer processing to ensure that this information alone is available.

We have thus shown that communication in sign language is possible using a highly stylized representation of the hands and body, at a considerably reduced information rate from a face-to-face situation. This demonstration suggests the possibility of developing a sign language telephone.

We acknowledge the assistance of Jay Jackson, Carol Furino, Cynthia Jefferey, Michael Androsko and Gene Marshall in testing our system. We also thank Lilah Axelsen for teaching us sign language, Eric Albert and Carol Furino for help in interpreting tapes, Carol Tipton and Susan Fischer for consultation about deaf communication and sign language, and Bela Julesz and Osamu Fujimura for helpful suggestions. A portion of this paper was presented at the Nato Advanced Study Institute: Sign Language Research, in Copenhagen, August 1979.

Simultaneous yet independent inheritance of somatically acquired tolerance to two distinct H–2 antigenic haplotype determinants in mice

R. M. Gorczynski

Ontario Cancer Institute, 500 Sherbourne Street, Toronto, Ontario, Canada M4X 1K9

E. J. Steele

Transplantation Biology Section, Clinical Research Centre, Harrow, Middlesex HA1 3UJ, UK

We have previously presented evidence that somatically acquired immunological tolerance to foreign histocompatibility antigens induced in male inbred mice can be transmitted at a high frequency to first- and second-generation offspring without exposure of the progeny to the tolerizing antigenic stimulus[1]. These data have in turn been interpreted to support a hypothesis predicting soma to germ-line inheritance for acquired states of the immune system[2]. Formal proof of this genetic scheme at the molecular level is not yet available. However, an even stronger reason for abandoning the notion of the isolation of the germ line from the soma (Weismann's doctrine[2]) would be provided by a clear demonstration of the multiple inheritance of independently acquired somatic characters. Here we present evidence that individual male mice (B10) made tolerant to two different H–2 haplotypes (B10.BR, B10.D$_2$) can transmit the tolerance state to each haplotype independently, yet often simultaneously, at a high frequency to both first and second generation progeny.

Congeneic resistant mouse lines (B10.SgN, $H\text{–}2K^bD^b$; B10.D$_2$, $H\text{–}2K^dD^d$; B10.BR, $H\text{–}2K^kD^k$) were purchased at 6 weeks of age and ATH mice ($H\text{–}2K^sD^d$) at 8 weeks of age from Jackson Laboratories. The latter mice were used within 4 weeks of arrival. Normal litters of B10.SgN (hereafter called B10) were produced in our animal room from the Jackson foundation stock; some members of these litters were mated (brother × sister) to produce normal B10 animals on a regular basis during the 10-month study. F$_1$ hybrids (B10 × B10.D$_2$, B10 × B10.BR) were produced by matings from the Jackson foundation stock. These served as a source of lymphoid cells both for inducing and maintaining tolerance in the B10 mice, and as normal responder or stimulator cells in the cytotoxic T-cell assays.

Tolerance was induced in neonatal B10 mice (produced at the start of the breeding programme) by intraperitoneal (i.p.) inoculation of 100×10^6 F$_1$ lymphoid cells (approximately 1:1 mixtures of bone marrow and spleen cells, Fig. 1; bone marrow only, Fig. 2). As previously reported, repeated injections of the same type of F$_1$ cells were given at 2-week intervals throughout the study (i.p. injections until 4 weeks of age—thereafter intravenous injections were given). While certainly not essential to produce operational tolerance in such neonatally challenged mice[3,4], we have continued these regular inoculations of F$_1$ hybrid cells, as discussed earlier, to ensure high levels of circulating F$_1$ hybrid cells in the neonates. No data are yet available to judge whether such repeated challenge is essential to induce the transmission of tolerance from parents to offspring which we have shown subsequently occurs (ref. 1 and below).

Tolerant male mice were chosen for mating with normal B10 females beginning at 8 weeks of age. Tolerance in these breeding fathers has been assessed by both cell-mediated lympholysis (CML) responsiveness (performed after partial splenectomy under ether anaesthesia) and skin graft rejection (see legends to Figs 1, 2). Only animals judged to be tolerant by both criteria

0028–0836/81/080678—04$01.00

have been used in the breeding studies reported. However, responsiveness in the progeny of such animals has been assessed initially only by *in vitro* assay (see below). Comparison of skin grafting and CML responses of the progeny is being investigated. First-generation progeny of these animals were reared without exposure to F$_1$ antigens. At 8 weeks, spleen cells of individual progeny mice were assayed *in vitro* for their ability to give rise to cytotoxic lymphocytes after stimulation with irradiated (B10 × B10.BR)F$_1$, (B10 × B10.D$_2$)F$_1$, or third-party ATH (H–$2K^sD^d$) spleen cells (CML assay). Target cells in the ^{51}Cr-release test were concanavalin A blasts of the respective spleen cells used as stimulators[4–6].

Typical data for first-generation progeny of B10 male mice made tolerant to B10.BR or B10.D$_2$ determinants are shown in Fig. 1. Clearly these first-generation animals show a high frequency (some 40–50%) of tolerance (0–5% specific cytotoxicity) to those determinants used to induce tolerance in their fathers (B10.BR, Fig. 1 *d*; B10.D$_2$, Fig. 1*e*). Note that not only is the ability of the progeny to respond to the third-party antigens (ATH) unaffected but so too is their ability to respond to B10.D$_2$ antigens (progeny of males tolerant to B10.BR) or B10.BR antigens (progeny of males tolerant of B10.D$_2$). It is also clear (Fig. 1*f*) that first-generation mice born to males undergoing the tolerance-inducing treatment procedure, but which failed to become tolerant, are phenotypically (in terms of CML responses) equivalent to the offspring of normal B10 mice. These results confirm our earlier findings on the genetic transmission of acquired tolerance to A-strain H–2 antigens in CBA mice[1], and extend the generality of the phenomenon to two additional mouse strain combinations.

Clearly acquired tolerance to B10.D$_2$ antigens can be inherited independently of tolerance to B10.BR antigens (Fig. 1). Interestingly, an apparent simultaneous transmission of tolerance to the independent K/D-end specificities associated with a given haplotype (for example, H–2^k) has occurred, as these specificities are themselves independently expressed on separate molecules. Although this in itself may represent the simultaneous transmission of tolerance to independent antigenic determinants, note that responsiveness to the distinct K/D specificities was not tested independently in the recipients described here, and alloreactive cytotoxicity directed to K end-encoded determinants is more readily demonstrated than to D end-encoded determinants. Thus one interpretation of our data would be that responsiveness to major stimulating antigen determinants (K end-encoded) only was recorded in the CML assays used and there is no need to postulate the parallel transmission of immunological tolerance to K^k, D^k in animals bred from males tolerant to B10.BR cells. Indeed, recent studies (unpublished) indicate the independent transmission of tolerance to K^k, D^d from B10 male mice made tolerant to B10.A lymphoid tissue and subsequently mated with normal B10 female mice.

We have investigated whether tolerance to two different specificities can be independently transmitted to progeny using a situation in which individual B10 males were rendered tolerant simultaneously to both H–2^k and H–2^d haplotypes. Hereafter we will make the minimum interpretation that we are measuring unresponsiveness to the major stimulating specificities (K^k, K^d) associated with those haplotypes. The data in Fig. 2 summarize results from first-generation progeny (of four such males) obtained over a 12-week breeding period. The data are arranged as response profiles to B10.D$_2$ or ATH antigens for progeny mice grouped into different levels of responsiveness (% specific cytotoxicity) to B10.BR antigens. (A similar plot is obtained if the progeny are grouped into different levels of response to B10.D$_2$.) Note: (1) All progeny mice respond to ATH antigens, irrespective of their response patterns to each of the other two antigens tested. (2) The response pattern to one haplotype is not predictive of the level of responsiveness obtained towards the other haplotype (for example, of 80 progeny hyporesponsive to B10.BR—$<10\%$ cytotoxicity—40 respond in the normal range to B10.D$_2$ and 40 are tolerant or low responders to B10.D$_2$). That is, in contrast to their fathers which are tolerant of both haplotypes, many of these first-generation offspring are now tolerant for either one or the other haplotype. (3) Many of these progeny also score tolerant (27/150) to or are low responders (13/150) of both H–2 antigenic types. These results therefore show that the inheritance of

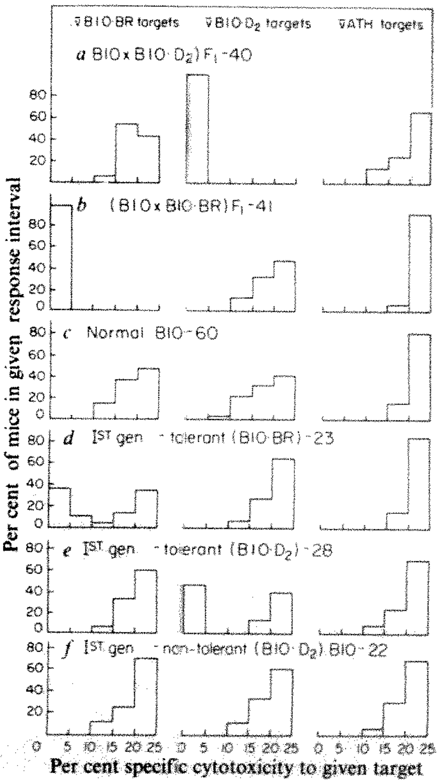

Fig. 1 CML response profiles of first-generation offspring of male B10 mice rendered tolerant to B10.BR or B10.D$_2$ antigenic determinants. Spleen cells (1.5×10^6 in duplicate) from individual 8-week progeny mice or control mice were stimulated in culture with irradiated (1,500 rad) spleen cells (5×10^5) of the relevant targets shown. Cytotoxicity was assayed at 5 days (refs 4–7). *a*, *b*, *c*, Responses of normal control mice (B10 × B10.D$_2$)F$_1$, (B10 × B10.BR)F$_1$ and B10 respectively. (The number of mice tested is indicated.) *d*,*e*, First-generation progeny of male B10, rendered neonatally tolerant to (B10 × B10.BR)F$_1$ (*d*) or (B10 × B10.D$_2$)F$_1$ lymphoid cells (*e*), mated to normal B10 females. All tolerant males used for breeding were specifically unresponsive to the tolerizing antigenic determinants in 5-day CML tests (performed in spleen lymphocytes obtained by partial splenectomy under ether anaesthesia) and retained a skin graft of the appropriate F$_1$ hybrid for at least 100 days (while rejecting third-party grafts in the expected fashion). No data from first-generation progeny born to animals not tolerant by these criteria are shown. Note that the efficiency of inducing stable tolerance in the present strain combinations was lower than in the previous study using (CBA × A)F$_1$ → CBA (ref. 1). Thus, of 9 male and 4 female B10 mice injected at birth with (B10 × B10.D$_2$)F$_1$, 4 males and 2 females scored tolerant by CML tests and 4 males and 0 females scored tolerant by skin grafting. Of 8 male and 5 female B10 injected at birth with (B10 × B10.BR)F$_1$, 4 males and 1 female were tolerant by CML and 4 males and 0 females were tolerant by skin grafting. Data shown represent cumulative data for progeny of all the tolerant (normal) fathers of a given type (at least 1 litter per father; minimum litter size, 4 offspring). Normal B10 mice tested were age-matched with tolerant progeny and were produced from mating seven normal male B10 mice with normal B10 femals. *f* Shows a limited study (22 mice) of the offspring to B10 mice inoculated neonatally with (B10 × B10.D$_2$)F$_1$ cells but shown thereafter (by CML and skin graft testing) to be fully responsive to B10.D$_2$ alloantigens. Offspring from all five males are included in this study (minimum litter size, 3). Cytotoxic data for individual mice were derived from 4-h ^{51}Cr release tests with an effector : target cell ratio of 2 : 1. total releasable c.p.m. and spontaneously released c.p.m. (arithmetic mean ± s.e.m.) for the different targets used were: B10.BR: 9,161 ± 139, 633 ± 11; B10.D$_2$: 10,132 ± 129, 931 ± 17; ATH: 8,149 ± 101, 576 ± 10. Assays for all targets and all effector populations were performed in triplicate. To test for significance between responses of normal B10 mice and progeny, response groups were compared using 2×2 or $2 \times 3 \chi^2$ tables. (For 2×2, responses grouped as $\leq 10\%$, $>10\%$ or $\leq 20\%$, $>20\%$ specific cytotoxicity; for 2×3, $\leq 15\%$, 15–20%, $>20\%$ specific cytotoxicity.) χ^2 and probability values are: response to B10.BR: *c* versus *d*, 29.7, $P < 0.001$; *c* versus *e*, 2.8, $P > 0.2$; response to B10.D$_2$: *c* versus *d*, 4.4, $P > 0.1$; *c* versus *e*, 28.6, $P < 0.001$; response to ATH: *c* versus *d*, 0.048, $P > 0.8$; *c* versus *e*, 1.2, $P > 0.2$.

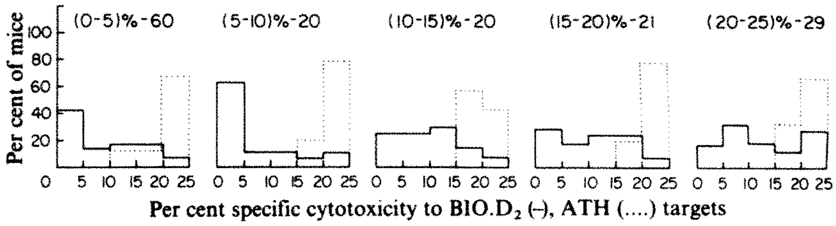

Fig. 2 CML response profile of first-generation progeny born to B10 males tolerized as neonates to both (B10×B10.D$_2$)F$_1$ and (B10×B10.BR)F$_1$ lymphoid cells. In this case B10 neonates were inoculated intraperitoneally with a 1 : 1 mixture of 50×10^6 bone marrow cells from the respective F$_1$ hybrid donors, and these inoculations were repeated every 2 weeks throughout the study. Spleen cells from 8-week-old progeny of matings of B10 animals known to be tolerant to both haplotypes (acceptance of skin grafts from both parents; unresponsiveness in CML cultures of spleen cells obtained by partial splenectomy) were stimulated in culture with irradiated (B10×B10.BR)F$_1$, (B10×B10.D$_2$)F$_1$ or ATH spleen cells and cytotoxic responses determined 5 days later. Individuals were then grouped according to their level of cytotoxic response to one tolerizing antigen (B10.BR) and the per cent of mice responding with a given degree of cytotoxicity (0–5%, 5–10% and so on) to the other two antigens recorded. Note (see Fig. 1 legend) that of 19 males and 8 females injected at birth with the bone marrow cell mixture, 6 males and 4 females were tolerant to both B10.D$_2$ and B10.BR in CML assays, and 4 males and 2 females were tolerant to both by skin grafting. As described in Fig. 1 legend, offspring from all 4 males are included in the data shown here (at least 1 litter per male; minimum litter size, 4 offspring). As in Fig. 1, cytotoxic assays were performed in triplicate at an effector: target cell ratio of 2 : 1. Total releasable c.p.m. and spontaneously released c.p.m. (arithmetic mean ± s.e.m.) for the targets shown were: B10.BR: 8,104 ± 106, 609 ± 11; B10.D$_2$: 9,112 ± 113, 613 ± 13; ATH: 7,048 ± 96, 596 ± 14. To test the null hypothesis that the response to B10.D$_2$ is independent of the response to B10.BR, a 3 × 3 table was constructed (response levels being ≤5%, 5–15%, >15% specific cytotoxicity). The $\chi^2 = 8.4$ and $0.05 < P < 0.1$ (null hypothesis cannot be rejected). The group significantly lower than expected (disturbing the rest of the table) was that group responding high to B10.BR (>15%) and low to B10.D$_2$ (≤5%), which contained fewer animals (11) than expected (18.7).

somatically acquired tolerance to two different H-2-encoded haplotypes is assorted at random in the first generation but that a high percentage show evidence for simultaneous transmission of these two specific tolerant traits.

Finally we examined the effect of breeding from the first-generation offspring—derived originally from male B10 mice tolerant to both B10.D$_2$ and B10.BR—on the subsequent transmission of the tolerant traits to second-generation offspring (in all cases only the original grandfathers were ever deliberately exposed to the tolerizing antigenic determinants). Three types of first-generation progeny were used as breeders: those which scored individually tolerant to B10.BR or B10.D$_2$ determinants (Fig. 3*a*, *b*) and those tolerant to both determinants (Fig. 3*c*). These assignments of parental phenotype were made on the basis of CML assays with spleen cells obtained by partial splenectomy.

The data of Fig. 3*a*, *b*, although limited to studies of only 27 and 15 individuals respectively, are clearly quite different from those of Fig. 2, and are, in fact, similar to those obtained by re-plotting the data of Fig. 1*d*, *e* in this format. Thus, first-generation progeny parents phenotypically tolerant to B10.BR give rise to second-generation offspring which respond to B10.D$_2$ antigens, yet which have retained their unresponsive phenotype for B10.BR antigens (Fig. 3*a*). Similar effects are also seen in the second-generation progeny derived from first-generation parents tolerant to B10.D$_2$ antigens (Fig. 3*b*). No unexpected reacquisition of tolerance for the other MHC haplotype was observed in any of the 42 mice tested (see below). In contrast to these patterns, first-generation progeny breeders scoring tolerant to both B10.BR and B10.D$_2$ antigens give rise to second-generation progeny (Fig. 3*c*) with the same 'spray' of cytotoxic response patterns as seen with the initial first-generation progeny (compare with Fig. 2). Some animals were tolerant either to B10.BR or B10.D$_2$ antigens, some were still tolerant to both antigens, and some had lost tolerance to both antigens.

In summary, investigation of the inheritance of neonatally acquired tolerance to major histocompatibility complex (MHC) gene products in congeneic resistant mice (using a B10 background) has shown that two separately determined tolerance phenotypes can be transmitted and assorted independently in first-generation progeny derived from matings of males tolerized to two H-2 haplotypes with normal females; and moreover, that a significant proportion of these first-generation progeny are also unresponsive towards determinants encoded by genes associated with both haplotypes. Transmission of these unresponsive traits is relatively stable as indicated by the fact that no spontaneous reversion (to the 'double' tolerance state) was observed in second-generation progeny which failed to display tolerance to one of the two H-2 haplotypes, and a significant percentage (16%, $P < 0.05$; see left-hand panels of Fig. 3*c*) of second-generation mice born to parents tolerant to both haplotypes still fail to respond to both, although independent assortment of the two responses can also be observed. These results suggest that genetic transmission of acquired tolerance to H-2 antigens may assort in a mendelian manner.

We noted what may be a more apparent than real dichotomy in the independent transmission of tolerance to $H\text{-}2^k$, $H\text{-}2^d$ haplotypes (from mice tolerant of B10.A), yet the simultaneous transmission of unresponsiveness to $H\text{-}2K^k$, $H\text{-}2D^k$ from mice tolerant of B10.BR. As we pointed out, we have not rigorously tested the response of mice to either K^k or D^k determinants (although independent transmission of tolerance to K^k, D^d does occur from B10 mice tolerant to B10.A MHC determinants, unpublished results). We reported previously a phenomenon of 'skipping' of expression of the tolerance phenotype in sequential generations of CBA mice made tolerant to (CBA×A)F$_1$ antigens[1]. Thus second-generation tolerant progeny are derived from apparently normal responder first-generation mice. In contrast, we recorded (Fig. 3) here a failure to detect 'reversion' or skipping) in sequential generations of mice. We cannot yet explain these differences, but it is not unreasonable to anticipate that they are due to inherent differences in the two experimental situations: for instance, to the ease with which tolerance can be produced in CBA (to A/J antigen) relative to the difficulty reported here in tolerizing B10 mice.

Finally, note the apparent difference in the behaviour (as assessed by CML response) of progeny mice derived from mating A-strain females with either A males neonatally tolerized to (A×B)F$_1$ cells or normal (A×B)F$_1$ males. In the latter case (A × A), offspring are not unresponsive to B antigens, despite the fact that tolerance to both A and B in F$_1$ mice presumably takes place after fusion of gametes. Nevertheless, the data presented here and elsewhere show that in the former situation the progeny acquire the tolerance phenotype of their parents. We cannot yet explain convincingly this anomaly; however, there are apparently many mechanisms whereby somatically acquired tolerance may be induced and maintained[7], and so far there is little evidence to indicate which, if any, of these mechanisms represents the natural mode of self/non-self discrimination.

The high frequency of parallel transmission of independently assorted, somatically acquired characters severely challenges Weismann's doctrine, and seems to us to demand an explanation not offered by conventional neo-darwinian genetics. It has been argued[2] that the type of phenomenon documented here and elsewhere[1,2,8,9], may be explained best by invoking the clonal selection and somatic mutation theory of immunology[10-13] and soma germ-line transmission of somatic genetic information (RNA) through endogenous RNA viral vectors and reverse transcriptase[14,15]. We might then imagine that genetic transfer of somatically selected information associated with the regulation of responses, for example, to A/J antigens in CBA mice[1] (anti-idiotype ?, antigen ?) is crucial for the anomalous inheritance patterns observed.

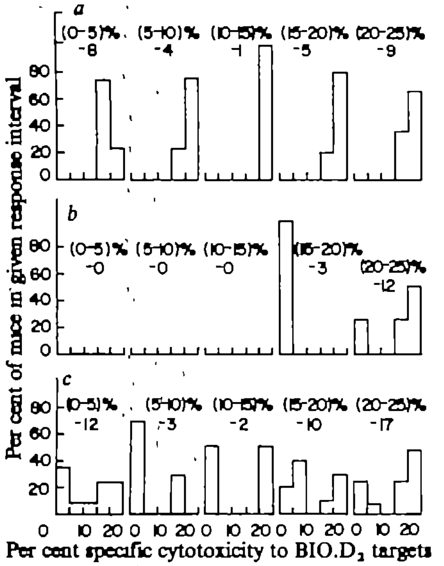

Fig. 3 Analysis of transmission of response patterns from first-generation progeny (Fig. 2) to second-generation progeny. Three types of first-generation progeny were used as parents to produce this data. In *a*, animals were selected (by CML tests performed after partial splenectomy) which were tolerant only to B10.BR stimulator cells—these first-generation progeny gave normal responses after stimulation with (B10×B10.D_2)F_1 cells. *b* Shows second-generation progeny derived from first-generation animals found to be tolerant only to B10.D_2 antigens. The data of *c* were derived from second-generation progeny born to animals found to have inherited the tolerance phenotype of the original male parents unresponsive to both B10.D_2 and B10.BR antigens). In all cases breeding was performed by mating either phenotypically tolerant males/females to normal females/males (outcross) or by incrossing of first-generation progeny with identical CML response phenotypes (earlier studies have suggested little difference in the gross inheritance of tolerance from such matings)[1]. Thus, for *a* the data are pooled from 5 litters from incross matings and 1 litter (5 progeny) of an outcross first-generation female; for *b* the data are pooled from 3 litters of 3 incross matings, while for *c* the data represent cumulative studies on 10 litters (≥1 per cage; minimum size, 4 mice) of 4 incross matings and 3 outcrosses (using first-generation tolerant female). The data of these second-generation progeny (total individual numbers tested for *a*, *b*, *c*, were 27, 15, 44 respectively) were grouped into response intervals for one antigen and the frequency of response in a given cytotoxic interval for the other antigen plotted (see Fig. 2). As in Figs 1, 2, cytotoxic responses after stimulation with ATH cells were also determined, but the pattern of response was not qualitatively or quantitatively different from that shown in Figs 1, 2 (all animals responded, irrespective of response status to B10.D_2 or B10.BR, data not shown). All data were obtained from the assays performed in triplicate at an effector:target cell ratio of 2:1. Total releasable c.p.m. and spontaneously released c.p.m. (arithmetic mean ± s.e.m.) for the different targets used were: B10.BR: 9,100±113, 689±16; B10.D_2: 7,068±94, 495±12; ATH: 10,351±129, 689±21. To test the null hypothesis that the response to B10.D_2 is independent of the response to B10.BR (*c*), a 2×2 table was constructed (≤15%, >15%) and an exact χ^2 test performed giving $P > 0.2$ (null hypothesis cannot be rejected).

We thank Susannah MacRae, Barbara Khomasurya, Susan Oliphant and Sue Bejasa for assistance. For critical comments on the manuscript we thank Drs Elizabeth Simpson, Bob Blanden, Arno Mullbacher and Jeff Pollard; and Walter Fierz and Steve Molnar for advice on statistics. This work was supported by the MRC of Canada (grant MA 5440) and the NCI of Canada. E.J.S. thanks the KIB Foundation (UK) for support.

B220: a B cell-specific member of the T200 glycoprotein family

Robert L. Coffman & Irving L. Weissman

Laboratory of Experimental Oncology, Department of Pathology,
Stanford University Medical Center, Stanford, California 94305

T200, a major cell-surface glycoprotein on lymphoid cells, exists in several forms with different electrophoretic mobilities. These forms have been correlated with different classes of lymphoid cell. The smaller forms, with molecular weights (MWs) of ≃170,000 and 180,000, are found predominantly on T cells while the 220,000 MW form is associated with B cells[1,2]. The polypeptide portions of each molecule may be identical or closely related as all three forms share the same allelic variations[3-5], and all reported heterologous antisera and monoclonal antibodies to T200 precipitate all three forms[2-6]. We report here a monoclonal antibody specific for the 220,000 MW form of T200 and show that it is expressed only on B cells and a subset of bone marrow cells which includes B cell precursors. We suggest that this form of the molecule be designated provisionally B220.

The hybridoma RA3-3A1 was produced by the fusion of the mouse myeloma S194/5.XX0.BU-1 with spleen cells from a rat immunized with the mouse cell line RAW 112, a pre-B cell tumour derived by infection of a mouse with the Abelson murine leukaemia virus[7]. The monoclonal antibody-secreting hybridoma RA3-3A1 was selected from the other fusion products because it produced an antibody that recognized RAW 112 cells and a subset of bone marrow cells, but not thymocytes. About 30% of bone marrow cells, 50% of spleen cells, 40% of mesenteric lymph node cells and less than 2% of thymocytes were positive when stained with the optimum titre of RA3-3A1 followed by fluorescein-conjugated rabbit anti-rat immunoglobulin. Flow cytometry analysis was carried out using the fluorescence-activated cell sorter (FACS III, Becton Dickinson, California). RA3-3A1 is an IgM and binds directly to the bacterium *Staphylococcus aureus*.

Immunoprecipitation of surface-iodinated spleen and RAW 112 cell lysates followed by SDS-polyacrylamide gel electrophoresis (PAGE) showed that RA3-3A1 precipitated a molecule with an apparent MW of 220,000 (Fig. 1). Precipitation of the same lysates with a monoclonal anti-T200 antibody gave the expected three bands from the spleen, the

0028-0836/81/080681—03$01.00

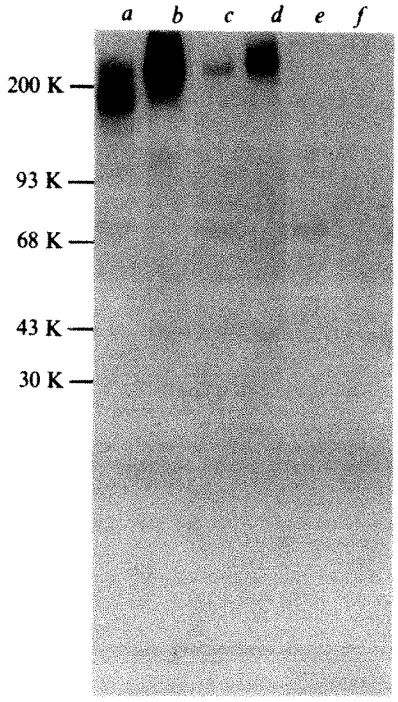

Fig. 1 Immunoprecipitation with RA3-3A1 and anti-T200. BALB/c spleen cells and RAW 112 cells were surface-iodinated by the lactoperoxidase method[8]. The cells were lysed with 1% NP40 in 0.01 M sodium phosphate buffer, *p*H 7.5, and the lysates clarified at 100,000*g* for 1 h. Aliquots of lysate from 2×10^6 cells were incubated with monoclonal antibodies and then precipitated with *S. aureus*[9] (for RA3-3A1 and control IgM) or *S. aureus* saturated with purified rabbit anti-rat Ig antibodies (for anti-T200). The rat anti-T200, prepared from the hybridoma 55-10.2 (ref. 10), was given by Dr J. A. Ledbetter. Control precipitates were prepared from rat IgM monoclonal antibody with no apparent reactivity to mouse cells. Immune precipitates were washed three times in 0.05 M Tris, *p*H 8.3, 0.45 M NaCl and 0.5% NP40, boiled in sample buffer with 1% β-mercaptoethanol and electrophoresed on 5–20% gradient SDS-polyacrylamide gels. The gels were run at 125 V for 1 h after the bromophenol blue marker dye ran off the end of the gel. The gels were then dried, fixed and autoradiographed on Kodak X-R film. Lanes *a*, *c* and are spleen cells; lanes *b*, *d* and *f* are RAW 112 cells; *a* and *b* are precipitated with anti-T200, *c* and *d* with RA3-3A1, and *e* and *f* with control rat IgM. Molecular weights are expressed in thousands (K).

Table 1 Identity of RA3-3A1$^+$ and RA3-2C2$^+$ populations in bone marrow and spleen

Cell fraction	% Cells stained with: RA3-3A1	RA3-2C2	Anti-κ
Whole bone marrow	32	28	10
RA3-3A1$^-$ bone marrow	3	3	1
RA3-2C2$^-$ bone marrow	2	2	1
sIg$^-$ bone marrow	19	19	3
Whole spleen	37	40	45
RA3-3A1$^-$ spleen	1	3	2
RA3-2C2$^-$ spleen	4	3	3
sIg$^-$ spleen	4	5	2

Spleen and bone marrow cells from BALB/c mice were stained with the appropriate antibody followed by a second stage with fluorescein-conjugated rabbit anti-rat Ig (for RA3-3A1 and RA3-2C2) or goat anti-rabbit Ig for the rabbit anti-mouse-κ. The reagents and details of staining and sorting procedures are described elsewhere[11]. The unstained fraction was isolated on the FACS III and samples restained as indicated. Sorted fractions contained 1–3% residual positive cells. The figures represent the per cent positive with the specific antibody minus the per cent positive in a control stain. The control for the rat monoclonals was an unreactive rat IgM monoclonal; for the anti-κ, it was specifically eluted rabbit anti-keyhole-limpet haemocyanin.

largest of which co-migrated with the molecule recognized by RA3-3A1. For RAW 112 cells the anti-T200 precipitated only one wide band centred around MW 220,000, which co-migrated with the band precipitated by RA3-3A1.

To test whether or not the 220,000 MW protein recognized by RA3-3A1 was the same as the large, B cell-associated form of T200, a surface-iodinated spleen cell lysate was precleared with anti-T200 or RA3-3A1 before immunoprecipitation and SDS-PAGE analysis with the two antibodies. Preclearing with anti-T200 removed all the bands precipitable by anti-T200 and also removed all the RA3-3A1-precipitable material (Fig. 2). However, preclearing with RA3-3A1 removed almost all the RA3-3A1-precipitable material, but seemed to remove only part of the 220,000 MW band. This is consistent with the observation (in Fig. 1) that RA3-3A1 does not precipitate as much 220,000 MW material as does anti-T200. This could mean that the 220,000 MW band precipitated by anti-T200 represents two or more antigenically distinct molecules, not all of which are recognized by the RA3-3A1 antibody. Alternatively, the determinant recognized by RA3-3A1 may be more labile than that recognized by the anti-T200, or the RA3-3A1 antibody may have a lower affinity for the molecule than the anti-T200 antibody. The precipitation of comparable amounts of μ chains from untreated and precleared lysates demonstrated that an unrelated surface glycoprotein was not removed by preclearing.

RA3-3A1 was shown to be specific for B cells and B cell precursors by comparing its staining distribution in the spleen and bone marrow with that of an anti-κ antiserum and another monoclonal antibody, RA3-2C2, which has been shown to be specific for B cells in peripheral lymphoid tissues and for B cells

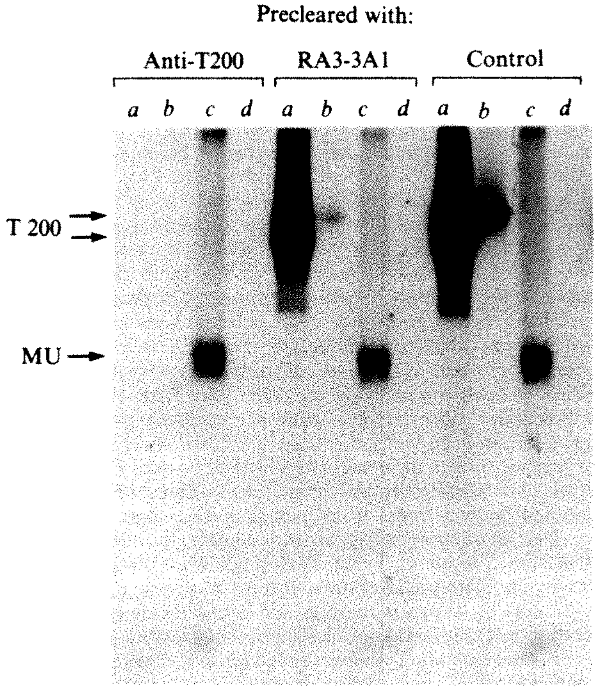

Fig. 2 Preclearing of surface-iodinated spleen lysate with RA3-3A1 and anti-T200. Surface-iodination, antibody precipitation and gel electrophoresis were performed as described in Fig. 1 legend. Preclearing of lysate aliquots was carried out before precipitation by adding a large excess of antibody to the lysates followed by two cycles of precipitation with *S. aureus* (for RA3-3A1 and control IgM) or *S. aureus* saturated with rabbit anti-rat Ig (for anti-T200). Precleared lysates representing 4×10^6 spleen cells were split into four aliquots and immunoprecipitated with: *a*, anti-T200; *b*, RA3-3A1; *c*, monoclonal rat anti-mouse μ chain; and *d*, control rat IgM. The T200 bands were deliberately overexposed to demonstrate the extent of the preclearing. Rat anti-mouse μ chain, produced from the hybridoma 151–119, was given by Dr J. Haaijman.

and sIg$^-$ lymphoid cells in the bone marrow[11]. Removal of sIg$^+$ or RA3-2C2$^+$ cells from the spleen by cell sorting removes all RA3-3A1$^+$ cells and, conversely, removal of the RA3-3A1$^+$ cells removes all cells that are sIg$^+$ and RA3-2C2$^+$ (Table 1). Thus, the molecule recognized by RA3-3A1 is expressed on all splenic B cells. A similar experiment with bone marrow cells again shows that RA3-3A1 and RA3-2C2 recognize the same population of cells, which includes B cells and ~20% of the sIg$^+$ bone marrow cells (Table I). These RA3-2C2$^+$, sIg$^-$ bone marrow cells include those which differentiate into sIg$^+$ cells in two days *in vitro*[11]. RA3-3A1 is therefore expressed on a fraction of sIg$^-$ bone marrow cells which consists of small lymphocytes and medium and large blast cells, and which includes at least some B cell precursors. Despite the similar staining properties of the two monoclonal antibodies, they seem to recognize different molecules. RA3-2C2 precipitates no molecules in the 200,000 MW range from surface-iodinated spleen cells, but it does precipitate a 50,000 MW protein from lysates of biosynthetically labelled lymphoid cells or tumours[12]. This p50 protein is not precipitated by RA3-3A1.

Because the form of T200 recognized by RA3-3A1 is expressed predominantly if not entirely by cells in the B cell lineage, we suggest that this molecule provisionally be called B220, and that the name T200 be reserved for the molecules found on thymus-derived lymphocytes.

We thank Dr William Raschke for the RAW 112 cell line, Drs J. Ledbetter and J. Haaijman for antibodies, and Dr Ian Trowbridge for helpful discussions. This work was supported by NCI fellowships CA 09302 and CA 06429 to R.L.C. and grants CP 91011 from the NCI, AI 09072 from the NIH and IM 56 from the American Cancer Society.

Induction of cell–cell channel formation by mRNA

G. Dahl, R. Azarnia & R. Werner

Departments of Physiology and Biophysics and of Biochemistry,
University of Miami, School of Medicine, Miami, Florida 33124

Intercellular junctional communication is very common in normal organized tissue[1]. It provides a pathway for transmission of electrical signals, especially in heart muscle[2,3], and may be important in differentiation and growth control[1,4]. The hydrophilic channels which enable cell–cell communication have been well characterized by biophysical methods[5,6], and there is now good evidence that they are contained in the nexus (gap junctions)[3,7–9]. Little, however, is known about the molecular mechanism of biosynthesis of junctional channels. Knowledge in this area has been obtained almost exclusively from experiments with reaggregated cells[10–15], a system complicated by the fact that *de novo* synthesis of channel proteins is obscured by reassembly of pre-existing subunits or utilization of precursors. To avoid these problems, we have now isolated mRNA from cells that are in the process of making new intercellular nexus with high efficiency, incorporated it via liposomes into communication-defective cells and have shown that the recipient cells established junctional communication.

We wanted a system where formation of junctions is controlled by an external stimulus and so chose uterine smooth muscle cells, because their response to stimulus is more pronounced than in the few other cell types where induction has been observed[16–20]. Normally, the cells of the myometrium do not exhibit synchronous contractile activity and have very few gap junctions. By contrast, during parturition when well synchronized activity of the cells of the myometrium is required for expulsion of the fetus, numerous large gap junctions are observed[16,17]. Although we have already reported that nexus formation in the myometrium can be induced in virginal females by injection of oestrogen[16], it was not clear whether this was due to *de novo* synthesis of junctional elements or to reassembly of pre-existing subunits. On the assumption that we were observing *de novo* synthesis of gap junction proteins[21–23] there should be present in these cells an increased number of mRNA molecules coding for these proteins shortly after stimulation with oestrogen.

To investigate this prediction we first obtained either a polysomal fraction or free mRNA from oestrogen-treated uterine tissue of rats. The polysomal fraction, or free mRNA, was then encapsulated into liposomes by the reverse-phase evaporation technique[24]. The phospholipid composition (phosphatidylserine/phosphatidylcholine) of the liposomes was chosen to ensure liposome–cell membrane fusion. Control experiments with liposomes containing fluorescent dyes, and electron microscopy, have shown that fusion was indeed a predominant form of liposome–cell interaction (R.A and G.D., unpublished results) (Fig. 1).

To test whether the injected mRNA coded for gap junction protein we measured its ability to induce intercellular communication between cells of the communication-defective Cl-1D mouse cell line[25]. In all experiments confluent cultures of

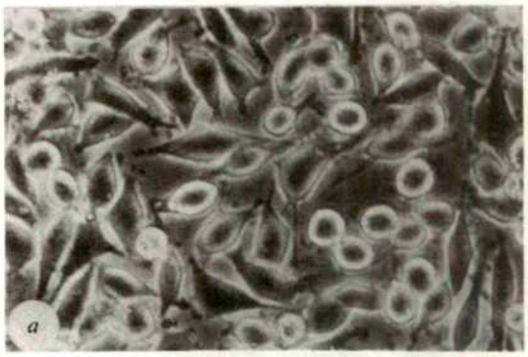

Fig. 1 Appearance of Cl-1D cells in bright field (*a*) and dark field (*b*) after incubation for 10 min with liposomes containing the fluorescent tracer substance carboxyfluorescein. The liposomes were prepared as described for the encapsulation of polysomes except that 100 mM carboxyfluorescein replaced the polysomes. All cells are highly fluorescent and even small cell processes contain sufficient tracer substance to outline them clearly.

0028–0836/81/080683—03$01.00

Cl-1D cells were first washed with serum-free minimal essential medium (MEM). The liposome preparation was diluted 1:3 (v/v) with serum-free MEM, and 1 ml of this suspension was added to a 9.6-cm^2 dish of Cl-1D cells. The incubation period was 1 h at 37 °C. The liposomes were then removed, and the cells washed repeatedly and incubated in normal culture medium. Thereafter random cell pairs were tested for electrical coupling (Fig. 2). Most cell pairs when tested 6 h after the removal of the liposomes were found to be electrically coupled (Table 1). The observed coupling ratios varied, but were consistently <1.0. Control cultures of Cl-1D cells were incubated in identical conditions with liposomes containing buffer only; no coupling was observed. Similarly, if the polysome preparation was treated with ribonuclease before liposomal encapsulation, no coupling developed. When cycloheximide was added to the cells immediately after the 1-h incubation period with mRNA-containing liposomes, the expression of the mRNA was drastically reduced; only 1 out of 13 cell pairs showed any coupling.

Although most of our experiments were done with polysome preparations we have obtained similar results with free mRNA isolated from oestrogen-induced uterine cells (Table 1). In contrast to polysomes, however, free mRNA had to be encapsulated at higher concentrations than polysomes to be as effective in inducing cell–cell coupling. This was not unexpected because the free mRNA was extracted from total cellular RNA whereas polysomes were obtained from a microsomal fraction known to be enriched for mRNA coding for membrane proteins. Thus, the free mRNA may have a lower specific activity than polysomes to induce cell–cell coupling.

Table 1 Incidence of electrical coupling in Cl-1D cells in control conditions and after loading with mRNA

Conditions of liposome treatment	Coupling incidence
Control: liposomes containing buffer only	0/29 (3)
Liposomes containing polysomes	77/114 (14)
Polysomes treated with ribonuclease before encapsulation	0/18 (2)
Cycloheximide (5 μg ml^{-1}) added after polysome loading	1/13 (2)
Free mRNA-containing liposomes:	
5 μg ml^{-1} mRNA	4/20 (2)
25 μg ml^{-1} mRNA	17/22 (2)

The number of cell pairs exhibiting electrical coupling (first number) and the total number of cell pairs impaled with microelectrodes and exhibiting stable membrane potentials (second number) show the coupling incidence. The number of experiments is given in parentheses. Coupling incidence was determined 6 h after treatment of the cells with liposomes. For obtaining the mRNA preparations, mature female virgin rats (Sprague–Dawley) were injected intramuscularly with oestrogen (Delestrogen, Squibb). Each animal received 10 mg of oestrogen per day for 3 days. On the fourth day the rats were killed and the uteri removed. (In some experiments the endometrium was removed by microdissection.) The uterine tissue from five rats was homogenized with an Ultra Turrax (Tekmar) homogenizer in 15–20 ml of buffer A (25 mM sucrose, 1.5 mM $MgCl_2$, 50 mM NaCl, 25 mM HEPES, *p*H 7.2). After centrifugation for 3 min at 5,000*g*, the supernatant was further centrifuged at 100,000*g* for 60 min. The pellet obtained in the high-speed centrifugation (microsomal fraction) was resuspended in 2 ml of buffer B (25 mM NaCl, 5 mM $MgCl_2$, 25 mM HEPES, *p*H 7.2) containing 0.5% (v/v) NP40 detergent. After incubation at 0 °C for 60 min and removal of insoluble fragments by centrifugation (10,000*g*, 30 min), the solution was layered on a discontinuous sucrose gradient containing 1 ml 2.5 M sucrose (in buffer B) and 2 ml 1.0 M sucrose (in buffer B), and centrifuged in a Spinco SW 50.1 rotor at 43,000 r.p.m. for 3 h. A polysomal fraction was recovered from the interface between the two sucrose layers. The polysomes were dialysed overnight against buffer C (1 mM EGTA, 15 mM KCl, 10 mM NaCl, 5 mM HEPES, *p*H 7.2), concentrated by freeze-drying to about 1 ml and dialysed again against buffer C containing 150 mM KCl. The volume of the final polysome preparation was adjusted to a concentration of $A_{260} = 2.0$–3.0 (ratio $A_{260}/A_{280} = 1.5$–1.6). Free mRNA was isolated by homogenization of uterine tissue in 4 M guanidine thiocyanate according to the procedure by Chirgwin *et al.*[27]. All equipment and containers used in these experiments were treated with dietyl pyrocarbonate (0.1%) for inactivation of RNase. The mRNA was further purified by adsorption to oligo(dT) cellulose[28]. For encapsulation of the mRNA preparations into liposomes, the reverse-phase evaporation technique[24] was used with the following specifications: 20 mg of phosphatidylserine and phosphotidylcholine (ratio 3:2) per 0.5 ml of aqueous solution of RNA. The liposome preparation was dialysed against Ca, Mg-free Hank's balanced salt solution (Gibco).

Studies of the time course of development of cell–cell coupling showed that coupling appeared within 2–4 h after removal of the liposomes (Table 2). At 4 h, about 40% of the cells were coupled, and this percentage increased still further until at 8 h practically all cells were coupled. The increase in coupling incidence was accompanied by larger coupling ratios. Later, the frequency of coupling declined and disappeared completely at about 30 h.

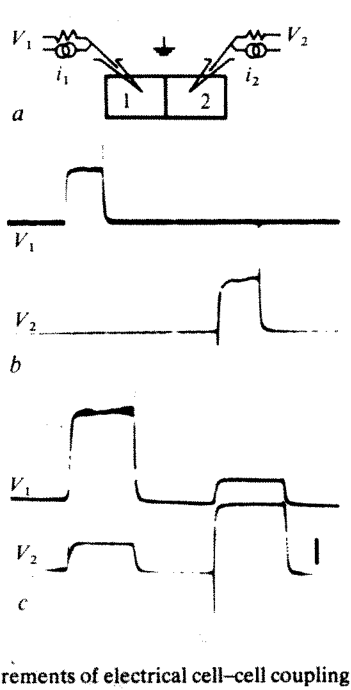

Fig. 2 Measurements of electrical cell–cell coupling. *a*, Electrode arrangement. Two neighbouring cells were impaled with a microelectrode each, which through a bridge circuit allowed current injection and recording of membrane potential. Oscilloscope traces: *b*, membrane potential in Cl-1D cells in control conditions; cells were incubated with liposome-containing buffer solution only. Current injection (10^{-8} A) into cell 1 results in hyperpolarization of this cell (V_1), which does not result in a voltage change in cell 2 (V_2). After a delay of about 150 ms, current is injected into cell 2, which results in change of membrane potential in this cell but not in cell 1. *c*, Membrane potential Cl-1D cells incubated with liposomes containing the mRNA preparation. Current injection in either one of the cells results in potential changes in both cells indicating electrical coupling. Calibration 50 mV.

Freeze-fracture electron microscopy[29] of mRNA-treated Cl-1D cells revealed the presence of nexus-like structures at the time when cell–cell coupling was present (Fig. 3). The observed structures consisted of aggregates of membrane particles resembling nexus which were associated with short ridges appearing like tight junctions. Similar structural arrangements have been found in myometrial tissue during early stages of nexus development after oestrogen treatment (G.D., unpublished results).

To determine whether the observed development of electrical coupling between Cl-1D cells occurs through newly synthesized channel proteins, the following potential artefacts must be ruled out. First, coupling could have developed because of fusion or partial fusion between neighbouring cells. Second, our polysome preparation may have been contaminated by channel

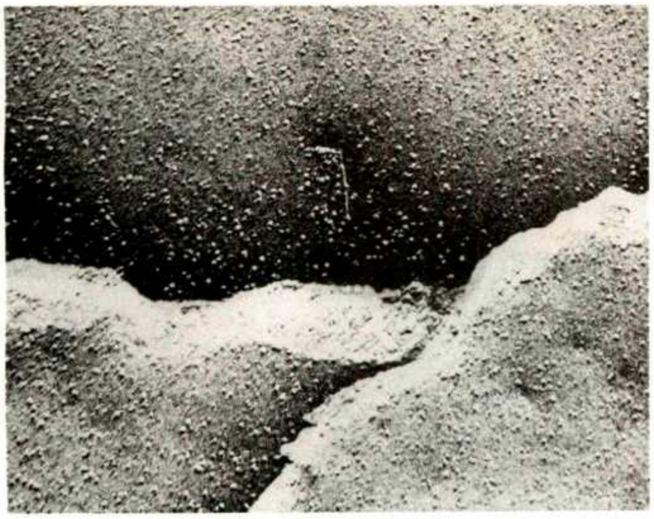

Fig. 3 Freeze-fracture electron micrograph of Cl-1D cells 6 h after incubation with liposomes containing the mRNA preparation. Within an area of membrane apposition a small aggregate of membrane particles can be seen associated with short ridges. ×60,000.

proteins of the uterine cells. Third, the liposome treatment by itself may have nonspecifically induced the development of cell–cell coupling in the recipient cell. Cell–cell fusion can be ruled out, as in all our experiments the observed coupling ratios were considerably below 1.0, whereas fusion should result in coupling ratios of 1.0 or close to 1.0, as has been shown with fusing myoblasts[26]. Furthermore, the control experiments with ribonuclease or cycloheximide indicate that mRNA is required and that protein synthesis is involved in the establishment of coupling. This argument is strengthened by the results obtained with free mRNA. Liposomes by themselves did not produce coupling. The time course of the development of coupling also seems to argue against an artefact. Polysomes from uterine cells that had not been treated with oestrogen did not produce any coupling. Finally, freeze-fracture electron micrographs show membrane junctions. Although the observed structures are not typical for nexus they resemble the structures that can be seen in the uterus shortly after oestrogen treatment. It is possible that the mRNA concentration is too low to induce fully developed nexus. This possibility is supported by the observed coupling ratios which are much lower than those observed in normal, coupled cells. Alternatively, junction formation may be a complex process requiring the participation of several factors some of which may not be under oestrogen control and, consequently, their mRNA may not be present at a high enough concentration in the polysome fraction.

It seems likely, therefore, that functional channels are present in the mRNA-treated Cl-1D cells but are not easily identified by electron microscopy because of the absence of typical multi-unit structures. Assuming that we are observing formation of regular cell–cell channels, we may conclude that their functional lifetime is of the order of 24 h. This seems to be a reasonable estimate because nexus have been observed for a similar period in myometrial cells at term[16]. Of course, the functional lifetime of intercellular channels in organized tissue may be quite different from that observed in cultured cells which are rapidly proliferating and, therefore, have a higher overall turnover rate. In conclusion, our results suggest that the induction of cell–cell coupling in rat uterus smooth muscle by oestrogen occurs by *de novo* synthesis of cell–cell channel proteins. Although this is the most straightforward interpretation of our results, we realize that alternative possibilities cannot be ruled out. For example, the introduced mRNA might code for a regulatory or morphopoietic protein involved in cell–cell communication. We believe that the system described here provides a promising model for obtaining information on the biosynthesis of junctional proteins not readily obtainable by conventional methods.

Block of Na current and intramembrane charge movement in myelinated nerve fibres poisoned with a vegetable toxin

J. M. Dubois & M. F. Schneider

Laboratoire de Neurobiologie, Ecole Normale Supérieure,
46, rue d'Ulm, 75230 Paris Cedex 05, France

In nerve membrane, the non-linear capacity current (displacement current) is assumed to reflect the movement of intrinsic membrane charges which control the opening of specific pathways for sodium ions (Na channels). However, various discrepancies have been reported between the effects of pharmacological agents on sodium and displacement currents (for a review see ref. 1). It is generally supposed that the opening and closing of Na channels constitutes one step of a multi-step system in which each configuration change may or not give rise to a measurable charge movement[2]. New drugs affecting either

0028-0836/81/080685—04$01.00

sodium or displacement currents may elucidate the relationship between charge movement and the control of sodium conductance. We therefore now report a comparison of the effects of a vegetable toxin (oenanthotoxin or OETX)[3] on both sodium current (I_{Na}) and intra-membrane charge movement (Q) in Ranvier nodes. We show that OETX reversibly blocks both sodium and displacement current. Studies of I_{Na} and Q during partial suppression by the toxin reveal differences in the effects of OETX on the remaining I_{Na} and Q. The findings are discussed in relation to recent models for the Na-channel gating process and for Na-channel block by local anaesthetics.

Oenanthe crocata is a highly poisonous plant[4,5]. The toxic substance, OETX, isolated from the roots, is a neutral ethylenic and acetylenic diol ($C_{17}H_{22}O_2$). In frog myelinated nerve fibres, OETX (0.1 mM) blocks the action potential and the sodium, potassium and displacement currents (present results and J.M.D., unpublished observations). The present experiments were carried out on voltage-clamped myelinated nerve fibres from the frog *Rana esculenta*. K current was abolished by adding tetraethylammonium (10 mM) to the external solution and by replacing the axoplasmic K content by caesium. Linear capacity and leakage currents were analogically subtracted from the total current[6]. Charge movement was recorded in the presence of tetrodotoxin (TTX, 10^{-6} M). To minimize noise and to obtain direct estimates of charge transfer, the current remaining after subtracting linear components was analogically integrated and then digitized and averaged. Typical recordings of charge transfer (integral of the asymmetrical capacity current) are presented in Fig. 1. In agreement with earlier reports[2,7], charge transfer followed a single exponential time course for moderate depolarizations ($E \leq 0$ mV). For larger depolarizations, two exponentials were required to describe the charge transfer kinetics.

External application of 60 µM OETX reversibly reduced Q (Fig. 1) and I_{Na} (Fig. 2) to 5–10% of their original values. These effects cannot be attributed to either fast (Fig. 3*c*) or slow[8] inactivation because they could not be removed by hyperpolarized holding potentials. The reduction of I_{Na} and Q were both independent of the frequency of stimulation. Recordings of sodium current and charge transfer obtained by intermittent application of saxitoxin during the development of OETX block indicated that OETX decreased I_{Na} and Q in parallel[9]. The leakage and the symmetrical capacity currents remained unchanged when I_{Na} and Q were virtually completely blocked by OETX (60 µM)[9].

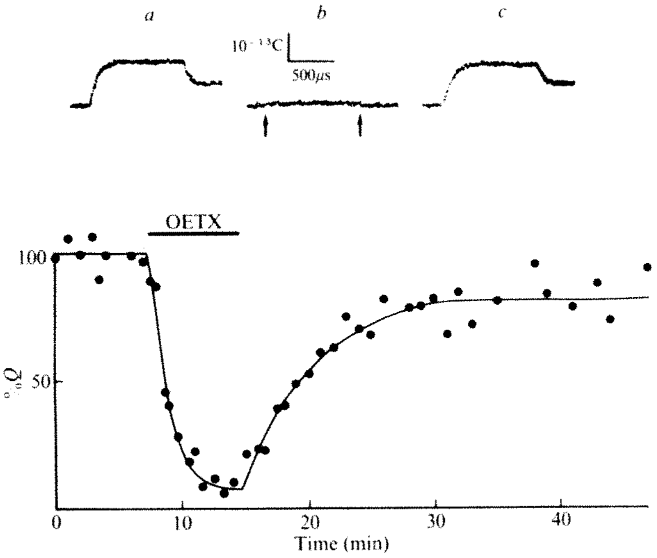

Fig. 1 Reversible immobilization of intra-membrane charges by OETX. The averaged integrated gating current was obtained in response to 12 100-mV depolarizing and 24 50-mV hyperpolarizing pulses from a holding potential of −100 mV. Temperature, 12 °C. Upper: *a*, in the control solution; *b*, in the presence of 60 µM OETX; *c*, after a 24-min wash with the control solution. Lower: relative amplitude of the charge transfer (Q) before, during and after the application of OETX (60 µM). The amplitude of Q was normalized to its mean value before the application of the toxin. Absolute charge and current amplitudes were in all cases calculated assuming a 10-MΩ internal resistance. A 4×10^{-2} solution of OETX in ethanol was diluted in Ringer's solution to give final toxin concentrations. Fibre 6-11-79 A.

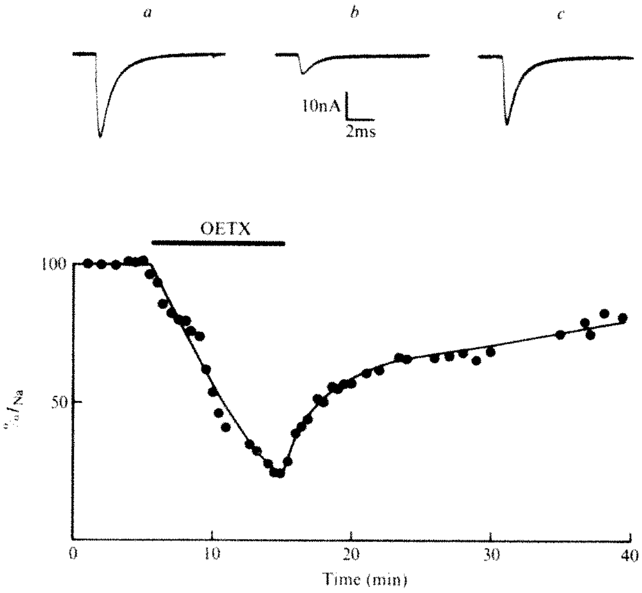

Fig. 2 Reversible block of I_{Na} by OETX. Sodium current was recorded at $E = 0$ mV after a 50-ms prepulse to −110 mV (control) or −140 mV (OETX). Holding potential, −70 mV. Temperature, 12 °C. Upper: *a*, in the control solution; *b*, in the presence of 60 µM OETX; *c*, after a 23-min wash with control solution. Lower: relative amplitude of peak I_{Na} before, during and after the application of OETX (60 µM). The amplitude of I_{Na} was normalized to its mean value before the application of the toxin. Fibre 13-11-79.

In addition to reducing I_{Na} and Q, OETX altered various properties of non-blocked Na channels. The fractional depression of peak I_{Na} produced by OETX varied with voltage (Fig. 3*a*), indicating that the Na-permeability activation curve was decreased in slope with a shift of its 50% point towards positive voltages (Fig. 3*b*). Similar results were obtained in four other fibres in which this point was investigated. In contrast, the position and relative steepness of the Q_{on}-voltage curve were not significantly modified by toxin treatment which reduced Q_{on} at 0 mV to 34–57% of control in three fibres (Fig. 4*a*). This is shown by Fig. 4*b*, in which the Q_{on} results in OETX are replotted with values for each fibre scaled up so as to compensate for the depression of Q by OETX. Both the data points in Fig. 4*b* and their best fit (dashed curve) by the two-state Boltzmann model (Fig. 4 legend) lie close to the fit (solid curve) to the control Q_{on} data from the same fibres which are reproduced from Fig. 4*a* in 4*b*. The effect of OETX on the Na-permeability activation curve cannot be attributed to a decrease in the series resistance artefact due to the smaller I_{Na} (ref. 10) because a reduction of I_{Na} to 40% of its original value by TTX (4×10^{-9} M) caused the Na-permeability activation curve to be shifted towards positive voltages by less than 2 mV (refs 9, 11). The time course of Na-current activation, determined after correction for a two-exponential inactivation process[12] in parallel, was either slightly delayed or not significantly affected by OETX[9], whereas the time constants for charge movement were reduced[9].

OETX markedly shifted the Na-inactivation curve towards negative potentials and slightly decreased its slope (Fig. 3*c*). The

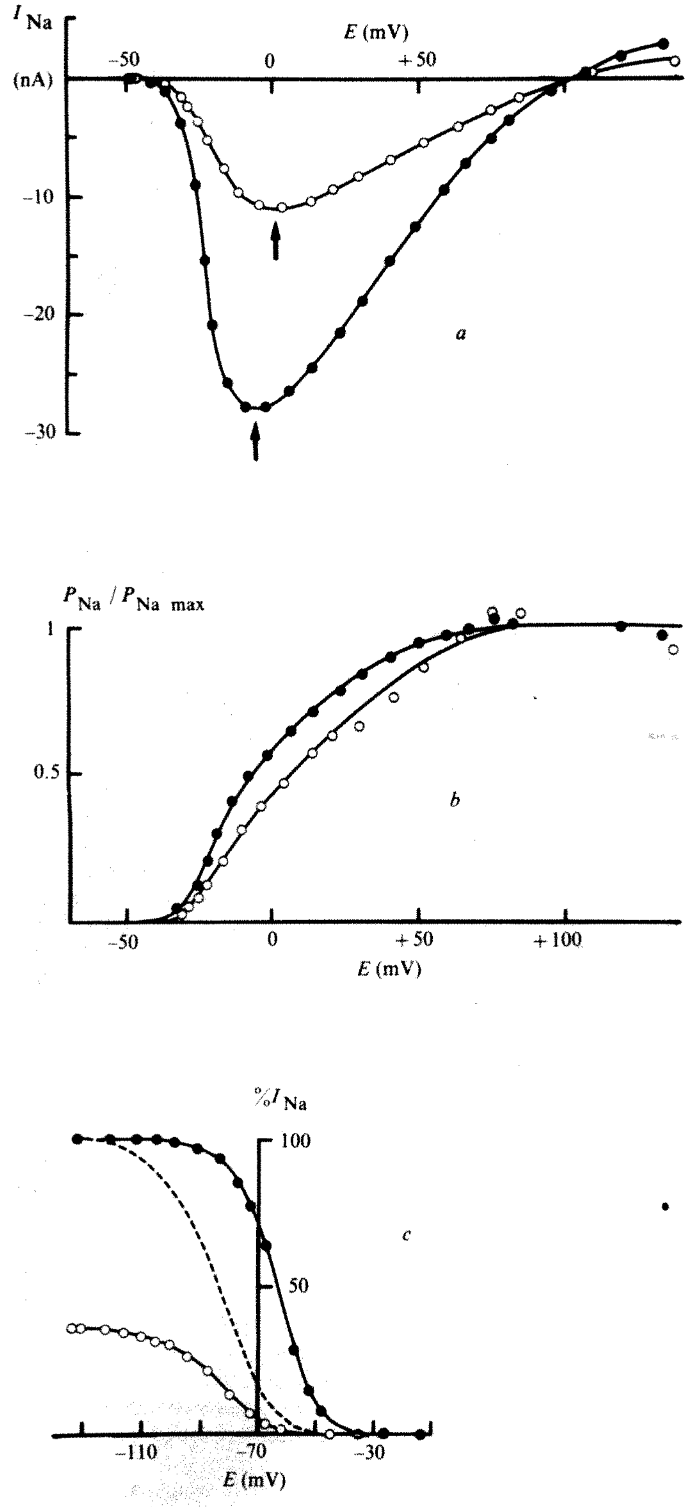

Fig. 3 Na current (*a*), Na permeability (*b*) and Na-current inactivation (*c*) voltage curves in control solution (filled circles) and during wash shortly after exposure to OETX (200 μM) (open circles). Holding potential, −70 mV. Temperature, 12 °C. *a*, The peak of I_{Na} was recorded during test pulses preceded by 50-ms prepulses to −110 mV (control solution) or −140 mV (during wash), so as to ensure complete removal of Na inactivation. Note that under the effect of toxin, the potential at which the inward current is maximum (arrows) is shifted towards positive values. *b*, Relative peak Na permeability (P_{Na}) as a function of membrane potential calculated from each set of results in *a* assuming the Na channel to rectify according to the constant field equation[19]. *c*, Available Na current (per cent of maximum control I_{Na}) as a function of membrane potential during a 50-ms prepulse. The dashed curve gives the results in OETX normalized to a maximum value of 100% for large hyperpolarizations. I_{Na} was measured at 0 mV. Fibre 26-2-79.

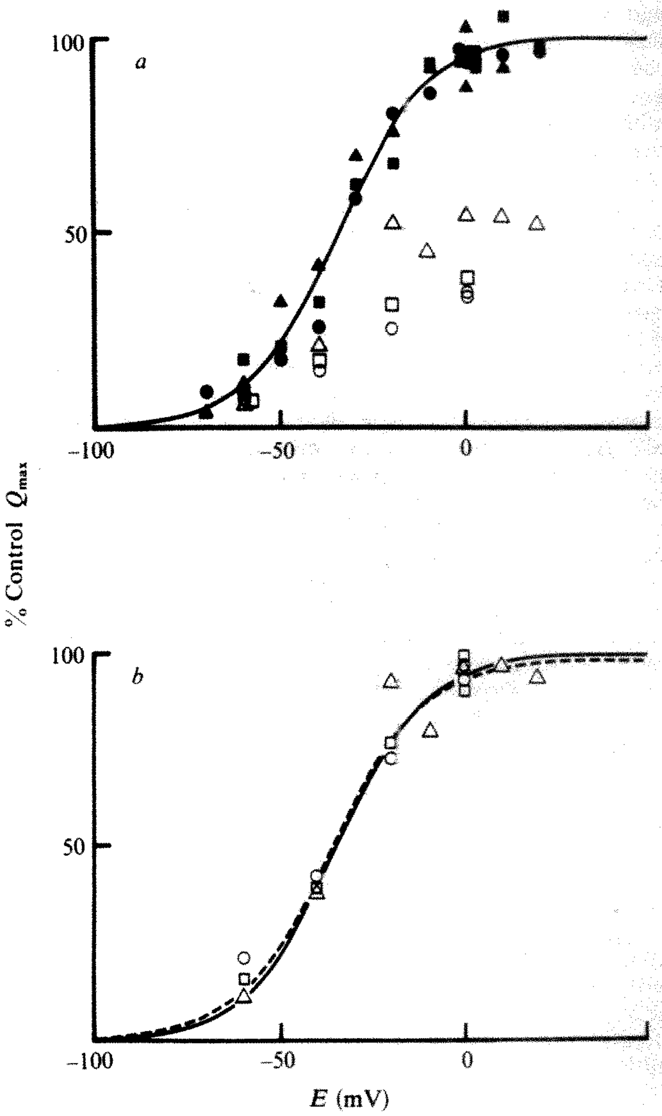

Fig. 4 Relative charge–voltage relationship in control solution (filled symbols) and in the presence of 40–60 μM OETX (open symbols). Holding potential, −100 mV. Temperature, 10–12 °C. *a*, Values obtained in both solutions on each of three fibres (different symbols) were first normalized to the mean control value of Q_{on} in that fibre at 0 mV. A non-linear least squares fit of the equation

$$Q_{on} = Q_{max}/\{1+\exp[(\bar{E}-E)/k]\} \qquad (1)$$

for the two-state Boltzman model[20–22] was first made to the combined values from the three fibres in control solution. All Q_{on} values were then normalized to the control Q_{max}. The values of Q_{max} (normalized), $\bar{E}$ and k obtained from the fit (curve) were 100%, −34.3 mV and 12.0 mV, respectively. *b*, Q values in OETX for each fibre were scaled by a constant chosen so as to minimize the squared differences between scaled values and the fit to the combined control data in *a*. The fractional values of Q in OETX determined from these scale factors were 35% (○), 57% (△) and 40% (□) of the control fit. Equation (1) was then fitted to the combined scaled OETX results, giving the dashed curve (Q_{max} = 98.1%, $\bar{E} = -36.4$ mV and $k = 12.6$ mV). The fit to the control data (solid curve) is reproduced from *a* for comparison. Fibres 15-10-79 (○), 6-11-79A (△), 21-12-79 (□).

kinetics of Na inactivation were accelerated[9] and the ratio Q_{off}/Q_{on} for a given pulse duration was slightly decreased.

Two major conclusions can be drawn from these results: OETX induces a reversible block of I_{Na} and charge movement, and in the presence of the toxin, the voltage and time dependences of the remaining sodium current and charge movement seem to be altered differently. Because the latter conclusion is based on measurements of OETX effects in different fibres with probable differences in toxin exposure, a quantitative comparison of toxin effects on I_{Na} and Q was not attempted.

In some respects, the effects of the uncharged toxin OETX seem to resemble those of the uncharged local anaesthetic benzocaine, which depresses both I_{Na} (refs 8, 13) and Q (ref. 14) and shifts and decreases the slope of the Na-inactivation curve[13]. However, whereas maximum attainable concentrations of benzocaine produce only partial depression of sodium current[8,15,16] and charge movement (ref. 14 and our unpublished observations), OETX can almost completely suppress I_{Na} and Q. This difference may be due to an inability to achieve sufficiently high benzocaine levels at the reactive channel site for all channels to react with drug, whereas OETX is sufficiently more soluble in the membrane or more reactive with the site to occupy almost all the sites.

In view of the similarities between the effects of OETX and benzocaine, it seems likely that the OETX effects on steady-state parameters may be accounted for by a general scheme for local anaesthetic action in which the drug can bind to the Na channel in each of its several states[13]. The depression of I_{Na} which cannot be restored by hyperpolarization would be due to OETX binding to resting channels. The shift and change in slope of the Na-inactivation curve would be explained by drug binding to open and inactivated channels. With this interpretation, the depression of Q would indicate that drug-blocked channels cannot undergo transitions between states, at least not transitions giving rise to detectable charge movement. Such a scheme for OETX action may perhaps also account for the modification of kinetic parameters. Alternatively, in addition to binding to the channel in its various states, it is possible that OETX produces the observed kinetic effects by acting at a different site from that at which it modifies the rate constants for channel transitions. In either case, the possibility of multiple transitions between resting and activated states[2,17], which may contribute differing amounts of Q, may perhaps account for the differences observed between OETX effects on the kinetics of I_{Na} and Q and on the voltage dependencies of sodium permeability and Q. The accelerated Na inactivation and decreased Q_{off}/Q_{on} are consistent with the suggested relationship between inactivation and charge immobilization[2,18].

We thank J. Louvel and Y. Chauvel for providing OETX samples and N. L. Sizto for running the curve fitting program. M.F.S. was on leave from the Department of Physiology, University of Rochester, Rochester, New York 14642.

Fibrinogen is the receptor for the endogenous lectin of human platelets

T. Kent Gartner*, J. M. Gerrard†, J. G. White & D. C. Williams*

Washed platelets activated by α-thrombin, γ-thrombin[1], thrombocytin[2] or the ionophore A23187 (ref. 3) lose their disk shape[4], produce pseudopodia and become cohesive. This cohesiveness is accompanied by the expression of an endogeneous haemagglutinin[5] which, although apparently bound to the platelet membrane[6], is dependent on cell secretion[7]. The interaction of this agglutinin with appropriate receptors on other platelets is believed to be responsible for aggregation. We report here that platelets can be prepared which lack agglutinin activity but have receptor function, that afibrinogenaemic platelets lack receptor activity, and that fibrinogen is the receptor for the agglutinin secreted by activated platelets.

Washed, fixed and non-fixed platelets were examined for thrombin-enhanced agglutinin activity using microtitre plates (Table 1). It is known that non-activated platelets do not express the agglutinin[5], and accordingly non-activated washed platelets did not agglutinate either themselves or fixed platelets. In contrast, platelets activated by thrombin agglutinated themselves and their agglutination titre was increased two- to four-fold by the presence of fixed platelets. The formaldehyde-fixed platelets, when treated with thrombin, neither agglutinated themselves nor fixed bovine erythrocytes which had receptors for the platelet agglutinin. Thus, the formaldehyde-fixed platelets had no agglutinin activity, which means that the apparent increase in the agglutination titre resulting from the presence of the fixed platelets was due to agglutination of the latter by the agglutinin of the thrombin-activated washed platelets. These results demonstrate that fixed platelets have functional receptors for the agglutinin but no functional agglutinin and that they did not cause activation of the washed platelets.

Agglutination of the fixed platelets by the activated washed platelets in the microtitre plate assays was blocked by the same compounds which block thrombin-induced platelet aggregation and enhanced haemagglutination[5] (see Table 2). Amino sugars and arginine completely abolished this activity whereas neutral sugars and other amino acids had no effect. Therefore, the binding specificity of the receptor on fixed platelets seems to be indistinguishable from that of either washed platelets or platelets in plasma[5].

In the course of characterizing platelets from patients with bleeding disorders, it was discovered that fixed platelets from a patient with congenital afibrinogenaemia[8] failed to enhance the agglutination titre of thrombin-activated platelets, which means that the fixed afibrinogenaemic platelets lacked agglutinin receptor function (Table 3). Furthermore, it was observed that this deficiency could be corrected if the afibrinogenaemic platelet-rich plasma was diluted 1:1, before fixation, with platelet-poor plasma from a donor who had a normal level of plasma fibrinogen. These results, and evidence that platelets from the afibrinogenaemic patient have no obvious plasma membrane deficiencies (D. R. Phillips, personal communication), led us to speculate that fibrinogen is the receptor for the secreted agglutinin expressed by activated platelets.

This hypothesis was tested by determining if fibrinogen could inhibit the expression of the enhanced haemagglutinin activity of activated platelets, the rationale being that free fibrinogen

Table 1 Fixed platelets lack agglutinin activity in microtitre plate assays

Diluted material	Fixed cells added	Titre
Washed platelets	None	0
Thrombin-activated washed platelets	None	2
Thrombin-activated washed platelets	Bovine erythrocytes	16*
Fixed platelets	None	0
Fixed platelets plus thrombin	None	0
Fixed platelets plus thrombin	Bovine erythrocytes	0

Agglutination of platelets was assayed in microtitre 'V' plates (Cooke Engineering Laboratory Products)[6]. 25 μl of Tris-buffered saline containing calcium (TCS buffer: 10 mM Tris, 2 mM $CaCl_2$, 150 mM NaCl, pH 7.4) was added to each well then 25 μl of the diluted material was added to the first in a row of eight wells and was serially diluted (× 2) in a series of six wells. The remaining two wells contained no diluted materials and served as controls. Finally, 25 μl of the fixed cells added were placed into each well, as either a suspension of fixed platelets (1×10^8 ml^{-1}) or a 2.5% suspension of trypsin-treated, formalinized bovine erythrocytes in TCS buffer[6]. Wells not containing fixed cells received 25 μl of TCS buffer and the contents of the wells were agitated gently. Each test was run in triplicate. Well contents were evaluated for agglutination after standing for 7 h at room temperature. The titre of a diluted material is defined as the reciprocal of the end point dilution (greatest dilution that gives agglutination). The platelets used as diluted materials were suspended in Tris-buffered saline containing EDTA (ETS buffer: 1 mM EDTA, 10 mM Tris, 150 mM NaCl, 0.2% α-D-glucose, pH 7.4) at a concentration of 10^9 ml^{-1}. Washed and fixed platelets were treated with thrombin by adding a final concentration of 0.25 U ml^{-1} of human thrombin (provided by Dr J. Fenton II) to the platelets, incubating the mixture for 1 min at 22 °C, adding it to the well and diluting immediately. Platelets were fixed by making a 1 : 1 dilution of platelet-rich plasma, obtained from blood drawn into ACD (2.5 g Na_3 Citrate. $2H_2O$, 2 g glucose, 1.5 g citric acid in 100 ml H_2O), into modified phosphate-buffered saline (40 mM PO_4, 150 mM NaCl, pH adjusted to 7.4 with NaOH) containing 0.5% formaldehyde and incubating overnight with gentle shaking. All operations were done at 37 °C. The fixed platelets were washed three times with TS buffer (10 mM Tris, 150 mM NaCl, pH 7.4) and suspended in TCS before use. Fixed platelets were used on the same day as they were washed. Suspensions of fixed non-activated platelets were birefringent, and the platelets had a disk shape when viewed in a scanning electron microscope. ADP treatment of the platelets (final concentration 5 μM ADP) before fixation typically decreased their receptor function—this may be caused by the generation of excess receptor activity but has not been tested.

* This agglutination was inhibited by a 30 mM final concentration of each of the following: L-arginine, α-D-mannosamine, α-D-glucosamine, and α-D-galactosamine but not by a final concentration of 60 mM glutamine, N-acetylglucosamine or N-acetylgalactosamine.

Table 2 Fixed platelets have receptor activity for the thrombin-enhanced agglutinin

Diluted material	Fixed cells added	Titre

Washed platelets	Platelets	0
Thrombin-activated washed platelets	None	2
Thrombin-activated washed platelets	Platelets	8*

Assays were performed as described in Table 1 legend.

* This agglutination was inhibited by the same compounds which inhibit thrombin-induced platelet aggregation and the function of the platelet-mediated enhanced haemagglutination activity of thrombin-activated washed platelets[5], that is, by a 30 mM final concentration of each of the following: L-arginine, α-D-mannosamine, α-D-glucosamine, and α-D-galactosamine but not by a final concentration of 69 mM glutamine, N-acetylglucosamine or N-acetylgalactosamine.

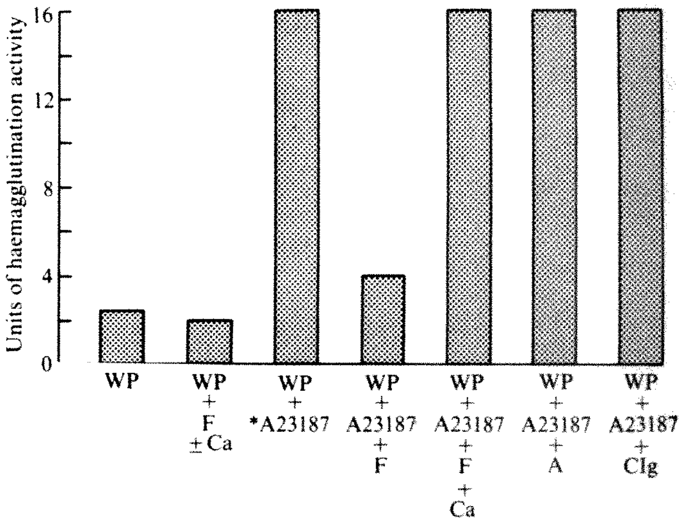

Fig. 1 Microtitre plate assays were carried out as described in Table 1. TS was the plate buffer and calcium ($CaCl_2$) was added where indicated at a final concentration of 2 mM. Platelets suspended in ETS were activated with one of the following: A23187 at 1 μg ml^{-1} (Calbiochem), α-thrombin at 0.25 U ml^{-1}, γ-thrombin at 5 μg ml^{-1} (both provided by Dr J. Fenton II), and thrombocytin at 5 μg ml^{-1} (supplied by Dr K. Stocker, Pentapharm). Human fibrinogen (L-grade, Kabi) treated with diisopropyl fluorophosphate[13], was used at a final concentration of 250 μg ml^{-1}. 125 μg ml¯1 of fibrinogen caused inhibition of half the maximum haemagglutination activity. Similar results were obtained using washed platelets activated with each stimulus listed above. Cold insoluble globulin (CIg, supplied by Dr K. Yamada[14]) was used at a final concentration of 125 μg ml^{-1}. Human serum albumin (Sigma) was used at a final concentration of 250 μg ml^{-1}. WP, washed platelets; F, fibrinogen; Ca, calcium; A, albumin; CIg, cold insoluble globulin. * The haemagglutination caused by washed platelets activated by A23187 was not inhibited by the supernatant fraction from heat-precipitated fibrinogen.

could compete with cells for the secreted agglutinin, if it functions as an agglutinin receptor. Washed platelets activated with α-thrombin, γ-thrombin, thrombocytin or A23187 were tested for enchanced haemagglutination activity in the presence and absence of fibrinogen. As shown in Fig. 1, fibrinogen completely inhibited the expression of the agglutinin in the absence of Ca^{2+} but had no effect in the presence of Ca^{2+}. The fact that fibrinogen did not inhibit the function of the agglutinin in the presence of Ca^{2+} explains why plasma fibrinogen would not be expected to inhibit the function of the endogenous platelet agglutinin *in vivo*. The inhibitory effect seems to be specific for fibrinogen because neither albumin nor cold insoluble globulin caused inhibition. These results may partially explain the observation that monovalent anti-fibrinogen antibody fragments drastically inhibited the aggregation of thrombin-activated washed platelets[9]. The basis of the ability of Ca^{2+} to eliminate the fibrinogen-induced inhibition of enhanced haemagglutination activity is unknown, but a possible explanation is that fibrinogen bound to platelets in the presence of Ca^{2+} has a much greater affinity for the agglutinin than does free fibrinogen.

The possibility that fibrinogen is the haemagglutinin was evaluated by the following tests. Fibrinogen itself was found to have no haemagglutination activity[7] (Fig. 1). Washed platelets suspended in ETS (see Table 1 legend) or Tyrode buffer were treated with fibrinogen and ADP (platelets in Tyrode buffer aggregated in response to stirring in the test conditions) and found to have no enhanced haemagglutination activity. Thus there is no evidence that plasma fibrinogen is the agglutinin, but our results do not exclude the possibility that platelet fibrinogen is the agglutinin. However, as there is evidence that platelet and plasma fibrinogen are identical[10], this possibility will not be considered further. The observations that amino sugars inhibit the binding of fibrinogen to ADP-treated platelets[11] does not elucidate whether fibrinogen functions as an agglutinin rather than a receptor for the agglutinin, but it does explain how these compounds can inhibit platelet aggregation[5].

Table 3 Agglutinin receptor activity of formaldehyde-fixed afibrinogenaemic platelets

Diluted material	Fixed cells added	Titre
Washed platelets	None	0
Thrombin-activated washed platelets	None	2
Thrombin-activated washed platelets	Control platelets	8
Thrombin-activated washed platelets	Afibrinogenaemic platelets	2
Thrombin-activated washed platelets	Afribinogenaemic platelets fixed in diluted control platelet-poor plasma	8

Assays were performed as described in Table 1 legend. The patient with congenital afibrinogenaemia had <10 μg ml^{-1} of plasma fibrinogen and <0.6 μg fibrinogen per 10^8 platelets.

The results described here demonstrate that the agglutinin of activated platelets is distinct from its receptor and that fibrinogen is the receptor for the agglutinin. According to these results and those already published[5,7], secreted materials, including proteins, mediate platelet aggregation by cross-linking adjacent platelets. This interaction of secreted agglutinin with platelets is mediated by fibrinogen—that is, fibrinogen links the agglutinin to the platelet plasma membranes. Fibrinogen, in turn, is probably specifically bound to the plasma membranes via membrane glycoproteins. The identity of these glycoproteins has not been reported, but evidence suggests that platelet glycoproteins IIb and/or III may be the fibrinogen receptors[12].

Non-uniform ion distributions and electrical potentials in sarcoplasmic regions of skeletal muscle fibres

D. G. Stephenson, I. R. Wendt & Q. G. Forrest

Department of Zoology, La Trobe University, Bundoora 3083, Australia

We report here electrophysiological and ion distribution results obtained with mechanically skinned skeletal muscle fibres which indicate that a Donnan equilibrium, characterized by large ionic concentration and electrical potential differences, is established between the myofibrillar space and the rest of the sarcoplasm surrounding the myofibrils. The more negative electrical potential within the myofibrils (−15 to −20 mV for conditions similar to those *in vivo*) can strongly influence: (1) intracellular Ca^{2+} movements associated with contraction; (2) the location of sarcoplasmic enzymes, their substrates and products of reaction; (3) measurements of the electrical potential difference between the extra- and intracellular space and estimation of relative membrane permeabilities for certain ions.

We used mechanically skinned single muscle fibres of the barnacle[1] (*Balanus nigrescens*), subsequently treated with a nonionic detergent which disrupted and removed all cellular membranes. Electron microscopic observations confirmed this and showed that the only regions which could be distinguished in the cross-section of the preparations after this procedure were the myofibrils and the inter-myofibrillar space.

Potential differences were measured between two glass micro-electrodes impaled into the skinned muscle fibre. As can be seen in Fig. 1, one could record either a very small or a relatively large potential difference regardless of whether both electrodes were in the preparation (Fig. 1*A, D*), or only one electrode was impaled in the skinned fibre while the reference electrode was kept in the surrounding solution (Fig. 1*B*). The results indicate that one of the regions within these skinned muscle fibres had essentially the same electrical potential as the surrounding solution, but that a second region yielded negative potentials of large amplitude relative to the bathing solution. When using low-resistance microelectrodes with an external tip similar in size to the diameter of myofibrils (2–3 μm), we were unable to record the large potential differences. This suggests that the former region may be associated with the space around myofibrils, whereas the latter may represent the myofibrils themselves.

The potential differences measured in these skinned muscle fibres did not change following the partial replacement of K^+

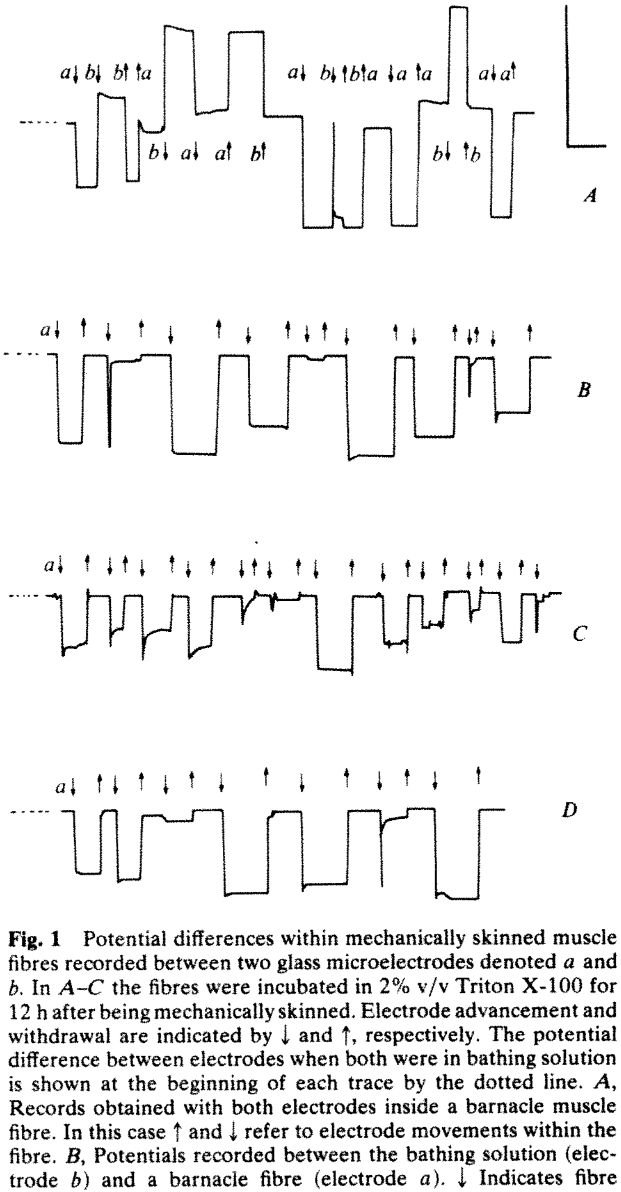

Fig. 1 Potential differences within mechanically skinned muscle fibres recorded between two glass microelectrodes denoted *a* and *b*. In *A–C* the fibres were incubated in 2% v/v Triton X-100 for 12 h after being mechanically skinned. Electrode advancement and withdrawal are indicated by ↓ and ↑, respectively. The potential difference between electrodes when both were in bathing solution is shown at the beginning of each trace by the dotted line. *A*, Records obtained with both electrodes inside a barnacle muscle fibre. In this case ↑ and ↓ refer to electrode movements within the fibre. *B*, Potentials recorded between the bathing solution (electrode *b*) and a barnacle fibre (electrode *a*). ↓ Indicates fibre impalement and ↑ withdrawal of the electrode into the bathing solution. *C*, Potential differences recorded from a toad iliofibularis fibre as in *B*. *D*, Records from a freshly skinned barnacle muscle fibre immersed in oil. In this instance the dotted line represents the potential difference between electrodes when just in contact with the fibre surface. The internal resistance of the glass microelectrodes (normally 40–80 MΩ when filled with either 2 M KCl or 4 M Na-acetate) was routinely measured when the electrodes were in solution and in the preparation to detect and discard artefactual potential measurements due to electrode tip blockage and/or damage. The external tip diameters and tip potentials of these electrodes were characteristically 0.1–0.3 μm and <5 mV, respectively. Input impedance $>10^{13}$ Ω. Composition of bathing solution for *A–C* (mM): EGTA, 10; Na_2ATP, 3; $MgCl_2$, 2; K^+, 100; trimethylaminoethanesulphonic acid (TES), 40; *p*H 7.10 adjusted with Cl. Calibration bars: vertical 30 mV; horizontal 30 s.

Abbreviations: Gly, glycine; BSA, bovine serum albumin; Carb, carbonic anhydrase; Chym, α-chymotrypsinogen A; Myo, myoglobin; Aldo, aldolase; Cyt *c*, cytochrome *c*; Mk, myokinase (see ref. 3 for M_r and pI values). To determine R_i, a substantial mass (60–100 mg) of skinned muscle fibres (~1 g of skinned fibres could be obtained from a single barnacle) was initially equilibrated in the appropriate solution containing the substance *i* and then transferred after careful blotting to an 'unloading' solution of specially chosen composition to allow accurate determinations of the amount of *i* carried by the known mass of skinned muscle fibres into the unloading solutions. For protein determinations the unloading solutions had the composition listed in the Fig. 1 legend and for $EGTA^{2-}$ and K^+ determinations the unloading solutions contained only 200 mM KCl and 100 mM Tris-HCl (*p*H 7.10), respectively. The concentration of proteins in the loading solutions was 10 mg ml^{-1}. This concentration of proteins did not have any significant effect on R_K, R_{EGTA} or ΔV measurements. Similar results were obtained in control experiments in which the concentration of BSA was varied between 1 and 50 mg ml^{-1}. The density of the fibres was also determined in various solutions by dividing the mass of the fibres by the volume they displaced in these solutions. The initial mass of the muscle preparations mechanically skinned under paraffin oil increased by 40–50% following the detergent treatment and equilibration in solutions containing 100 mM K^+. Their mass increased further after equilibration in solutions with a higher ionic concentration[9]. The following analytical methods were used for the various R_i determinations: R_{EGTA}, titration method of Moisescu and Pusch[10]; R_{Gly}, spectrophotometric method using glycine reaction with ninhydrin; R_{protein}, trichloracetic acid precipitation followed by Lowry's method for protein determinations: $R_{Cyt\,c}$, both Lowry's method and direct spectrophotometric measurements; R_K, atomic absorption spectrophotometry.

* Composition of solutions as in Fig. 2 legend.

† $RT/F = 25.5$ mV.

‡ Interpolated values.

with Na^+, indicating the absence of a selective barrier, such as a membrane, between the two regions. An increase in $[Ca^{2+}]$ from $\sim 10^{-8}$ M to 10^{-5} M also did not result in any significant change in the potential differences recorded. However, an increase in $[Mg^{2+}]$ from ~0.2 to 5 mM resulted in a significant decrease in the potential difference between the two regions (~5 mV for solutions similar to those in Fig. 1). Relatively large potential differences could also be recorded in mechanically skinned amphibian muscle fibres (Fig. 1*C*) and in freshly skinned barnacle muscle fibres immersed in oil (Fig. 1*D*).

To characterize further the potential difference (ΔV) between the myofibrillar space and extra-myofibrillar space, we investigated the effect on ΔV of varying the concentration of KCl in the bathing solution. As can be seen from Fig. 2, ΔV decreases with an increase in the ionic concentration of the solutions in a fashion similar to that expected for a Donnan potential[2].

An important inference from the existence of a Donnan equilibrium between different regions of the muscle fibre is the non-uniform distribution of ions in this cell, and we have used the same skinned muscle preparation to determine the distribution of ions between the myofibrillar and extra-myofibrillar space. The extra-myofibrillar region of the skinned muscle fibre can be considered as an extension of the space surrounding the preparation which is in electrochemical (Donnan) equilibrium with the space between myofilaments. If there was an important difference in the ionic composition between the myofibrillar and extra-myofibrillar space due to a Donnan-type equilibrium produced by negatively charged myofilaments, the ratio, R_i of the average concentration of an ion *i* in the preparation to the concentration of the same ion in the bathing solution, would be expected to be significantly higher for cations than for anions (see Table 1 legend for methods used to determine R_i). This is confirmed by the results shown in Fig. 3, where the ratios for K^+ and $EGTA^{2-}$ have been obtained simultaneously in the same solutions and the same batch of skinned fibres from a single barnacle. The average values for R_K and R_{EGTA} obtained over all experiments are given in Table 1.

Figure 3 and Table 1 also show the R_i values for glycine, a small uncharged molecule, which would be expected to penetrate freely the space between myofilaments. The value of R_{Gly} can be used as an index of the fraction of total fibre volume available for diffusion (S_d), and these results indicate that most of the space within our preparations is free for diffusion in all the ionic conditions used. The fraction of total fibre volume which is extra-myofibrillar (S_e) can be estimated directly from the value of R_i of a relatively large, negatively charged protein which cannot enter the myofibrillar space and we have used bovine serum albumin (BSA, M_r 68,000, *p*I 5.89)[3] as a marker for this purpose. The values of R_{BSA} are shown in Table 1. If R_{BSA} is equated to S_e, it can be seen that the extra-myofibrillar space would represent more than 50% of the total volume of these skinned muscle preparations. Indeed, electron micrographs also indicate that large areas of extra-myofibrillar space exist in extensive parts of these Triton-treated skinned muscle fibres.

If the ions are in electrochemical equilibrium in the preparation, one can predict an average value for the electrical potential difference ($\Delta V^i_{\mathrm{pred}}$) between the myofibrillar and extra-myofibrillar space from the Nernst equation for each ion *i*. Using the experimentally determined values for R_i and assuming, for simplicity, that $R_{Gly} = S_d$, $R_{BSA} = S_e$ and the activity coefficients of the respective ions are similar in the myofibrillar

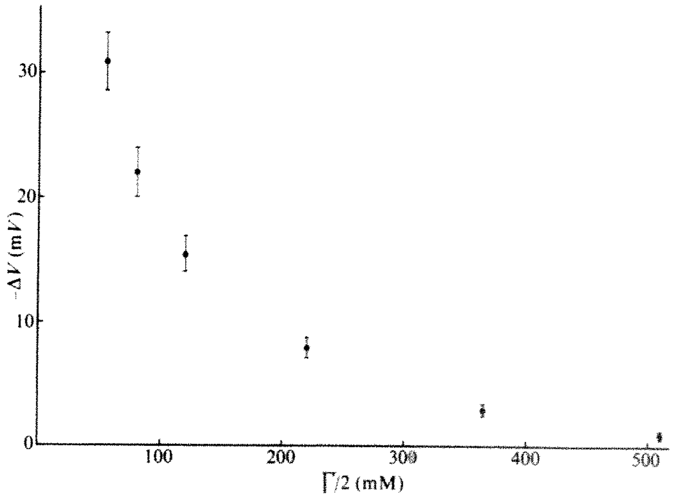

Fig. 2 Effect of ionic strength (Γ/2) on the average potential differences measured in mechanically skinned muscle fibres of the barnacle. The points represent the mean values (±s.e.m.) obtained from fibres of six different barnacles. Each fibre was impaled at least 30 times in each solution and care was taken to distribute the impalements over many regions of the fibre. The ionic strength was varied by adding differing amounts of KCl to a basic relaxing solution containing (mM): TES, 40; K_2EGTA, 10; Na_2ATP, 3; $MgCl_2$, 2. The final *p*H was adjusted with KOH to 7.10 in all solutions.

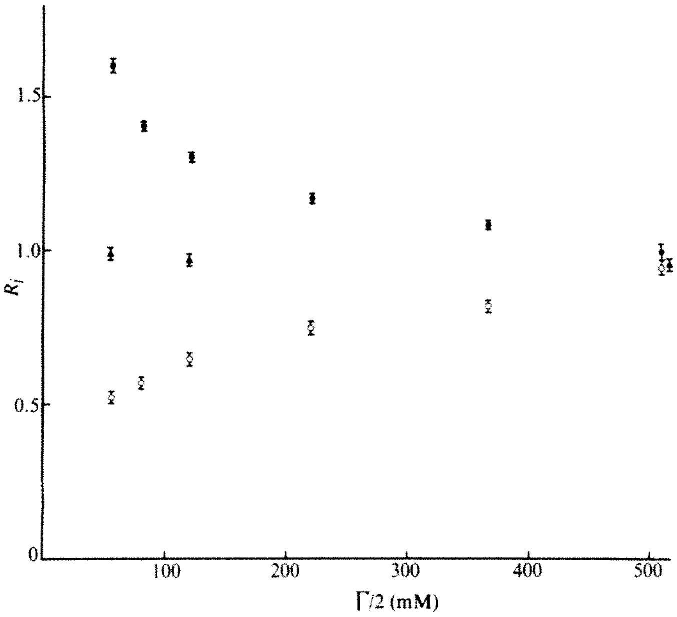

Fig. 3 Effect of ionic strength (Γ/2) on average values of R_{EGTA}(○), R_K(●) and R_{Gly}(▲), measured simultaneously in the same batch of skinned barnacle muscle fibres (200–300) from one animal. The vertical bars indicate the error of the methods (see Table 1). Note that R_{EGTA} is significantly smaller than R_K in all solutions but that of highest ionic strength and that the discrepancy between R_K and R_{EGTA} increases with decreasing ionic concentration in the solutions, as expected if a Donnan equilibrium was mainly responsible for the distribution of ions in these muscle preparations.

space and in the bulk solution, the predicted ranges for ΔV (ΔV^{K}_{pred} and ΔV^{EGTA}_{pred}) shown in Table 1 were obtained from the following equation

$$\Delta V^{i}_{pred} = (RT/n_iF)\ln(S_d - S_e)/(R_i - S_e)$$

In addition to BSA, the distribution of several other proteins of differing molecular weight and *p*I were investigated and their R_i values are listed in Table 1. The R_i values for the proteins of $M_r < 20{,}000$ approach the value for R_{Gly} as the ionic strength of the solutions increases, suggesting that there was no specific binding other than an electrostatic type of interaction between filaments and cytochrome *c*, or myoglobin, and that there was no steric restriction for the diffusion of these proteins between myofilaments. Cytochrome *c* and α-chymotrypsinogen A are both highly positively charged at *p*H 7.00 and show much larger values for R_i than does K^+ in conditions where a significant potential difference exists. Myoglobin is only slightly charged in these solutions and accordingly has an R_i value smaller than R_K.

The other proteins, carbonic anhydrase, aldolase and BSA, show a significantly smaller R_i value than R_{Gly} in the presence of 500 mM K^+ compared with $R_{EGTA} \simeq R_K \simeq R_{Gly}$, suggesting that these proteins are sterically restricted to certain degrees from entering the myofibrillar space. Of these proteins only aldolase is highly positively charged and if free to diffuse between myofilaments it would have been expected to have R_i values close to $R_{cyt\,c}$, which is not the case. However, the R_i value for aldolase is significantly higher than R_{BSA} for lower ionic strength solutions and this could be due to an increased concentration of aldolase in the outer layers of myofibrils due to the negative potential differences. These results on protein distribution: (1) strongly support the existence of a significant Donnan equilibrium within muscle fibres, (2) indicate that steric restrictions can become significant for the diffusion of proteins with $M_r >$ 20,000–30,000 and (3) suggest that the location of sarcoplasmic biochemical reactions would be determined by the charge and the size of the molecules involved. An interesting corollary from these experiments is that the prevailing electrical potential configuration within skeletal muscle fibres would promote a rapid activation of contraction by selectively facilitating the diffusion of Ca^{2+} released from the sarcoplasmic reticulum towards the area of the filament lattice with the highest negative charge density (region of filament overlap), where force is generated.

Previous attempts to record electrical potential differences between bundles of glycerinated muscle fibres[4–6] and the bathing solutions, and between mechanically skinned muscle fibres[7,8] and the bathing solutions have been reported. However, doubts have been raised about the state of membranes in the multicellular glycerinated preparations[6] and more recent observations on mechanically skinned muscle fibres indicated either a complete absence or drastically reduced potential differences[7,8] between the skinned muscle preparations and the bathing medium. The present results, obtained using several independent measurements, show that in the absence of any cellular membranes a significant electrical potential difference exists between regions within these muscle fibres and that electrically charged substances are not uniformly distributed within muscle fibres at physiological levels of monovalent cations.

Rhythmic contractile activity of the *in vivo* rabbit aorta

Allen Mangel, Mohammad Fahim
& Cornelis van Breemen

Department of Pharmacology, University of Miami School of
Medicine, PO Box 016189, Miami, Florida 33101

The cellular element of the aorta is largely smooth muscle; yet this organ has long been regarded as a passive elastic tube[1–4], without regard for the possible function of its smooth muscle cells. The isolated rabbit aorta became popular as a convenient smooth muscle preparation[5], and much has been learned about its cellular physiology, but unfortunately the functional role of this tissue was lost on its excision. Like many mammalian arterial preparations, the isolated aorta either fails to show spontaneous electrical or mechanical activity, or shows activity of a much slower frequency than the rhythmic activity of the heart[6,7], thus obscuring any possible relationship with the pulsatile activity of the heart. However, contractions are elicited from the isolated aorta on stimulation with various neural and hormonal agents[5–10]. In effect, the aortic smooth muscle has been classified as multiunit, which suggests that physiological activation may be neurogenic[11]. Thus, removal of the muscle from the body may result in disruption of the neural connections which function in normal activation of contraction. We show here that when recordings of aortic tension are made *in vivo*, rhythmic contractions are observed. Evidence is presented which indicates that the contractions are neurogenic in origin and exhibit a precise phasing pattern with the pulse wave.

A longitudinal cut was made along the abdominal midline of rabbits anaesthetized with an intravenous injection of Nembutal (35 mg per kg) through the ear vein. The abdominal aorta was exposed, and the blood flow from a 5-cm section was bypassed using a polyethylene tube (Fig. 1). In the centre of the bypass tube, a catheter was mounted and connected to a blood pressure transducer (Statham P23Db). An isometric tension transducer (Grass FTO3C) was attached to the bypassed muscle segment such that simultaneous pressure and tension recordings could be made. These recordings were made at loci equidistant from the heart.

Illustrated in Fig. 2 are simultaneous recordings of pulse pressure, measured in the bypass tube, and muscle tension, recorded from the bypassed muscle segment. The pressure waves and muscle contractions exhibited a 1 : 1 correspondence with the phasing between the two events, displaying a definite relationship. During the pressure wave diastole, muscle tension was maximum. Generally, within 20 ms after the initiation of an increase in pressure, the muscle began to relax and tension was usually at a minimum by a time corresponding to the dichrotic notch. As pressure began to decline again, muscle tension once again increased. This increase in tension was characterized by two components, a fast and a slow phase. The relative duration of the two phases varied somewhat from preparation to preparation. Such a cyclic pattern of simultaneous pressure and tension changes was observed in 10 of 10 animals tested.

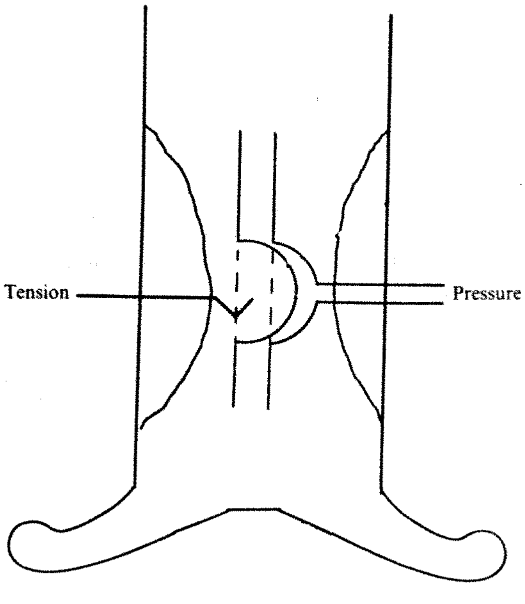

Fig. 1 Schematized recording technique for simultaneous measurement of pressure and tension in rabbit aorta. Dotted lines indicate bypassed muscle segment.

The possibility that the tension recordings were produced artefactually by body movements secondary to the pulse wave was eliminated by the lack of parallelism between the two recordings. Local application to the bypassed aortic muscle segment of the calcium flux inhibitor lanthanum (3 mM), local anaesthetics xylocaine (1%) and tetrodotoxin (10^{-7}–10^{-6} M), or the α-adrenergic blocker phentolamine (10^{-4} M) inhibited or abolished the contractions without affecting the pulse pressure. The contractions were enhanced by local application of atropine (10^{-4} M) or noradrenaline (10^{-6}–10^{-5} M), again without any effect on pulse pressure. If, on the other hand, noradrenaline (10^{-6} M) was administered parenterally through the ear vein, the pulse pressure increased while the contractions in the bypassed segment either decreased in amplitude or remained unchanged.

The abolition of the contractions by tetrodotoxin indicates that their propagation is neurally mediated. This premise was further investigated by measuring the direction and conduction velocity of the contractile wave. Figure 3 illustrates the effects of interrupting the anatomical continuity of the aorta on either side of the segment from which the contraction recordings were made. If the aorta was severed cranially (upstream), the contractions ceased completely (Fig. 3*b*), whereas after a distal cut contractions continued (Fig. 3*a*). The signal for contraction is therefore conducted in the same direction as the pulse wave. To measure the velocity of conduction, we bypassed two segments of the aorta and recorded contractions at two locations, the distance between which was accurately measured. The time interval between the onset of the contractions yielded a conduction velocity of 1.9 m s^{-1} directed caudally, a similar conduction velocity to that found for the pressure wave[12]. This velocity falls well within the range of neural activity[13,14] but is much faster than the propagation velocity observed for myogenic phenomena in other types of smooth muscle[15,16].

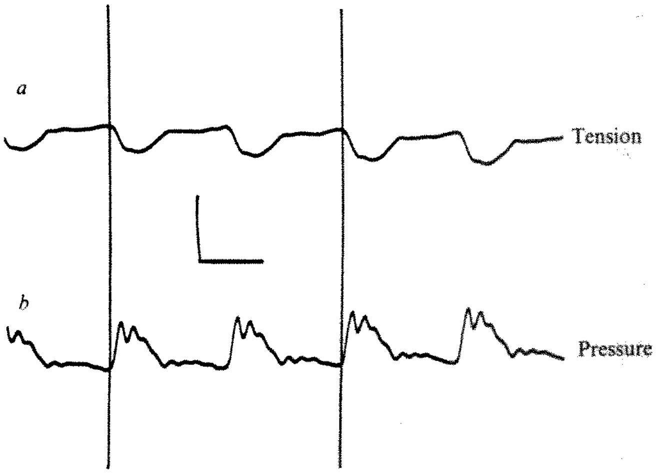

Fig. 2 Simultaneous recording of tension (*a*) and pressure (*b*) from the *in vivo* rabbit aorta. Time mark lines are drawn to coincide with the onset of the pressure wave. Scale bar: 0.6 g, 30 mm, 120 ms; basal blood pressure is 76.0 mm. An upward deflection reflects an increase in tension and pressure.

From the above results, we conclude that neural impulses activate waves of smooth muscle contraction, travelling with the

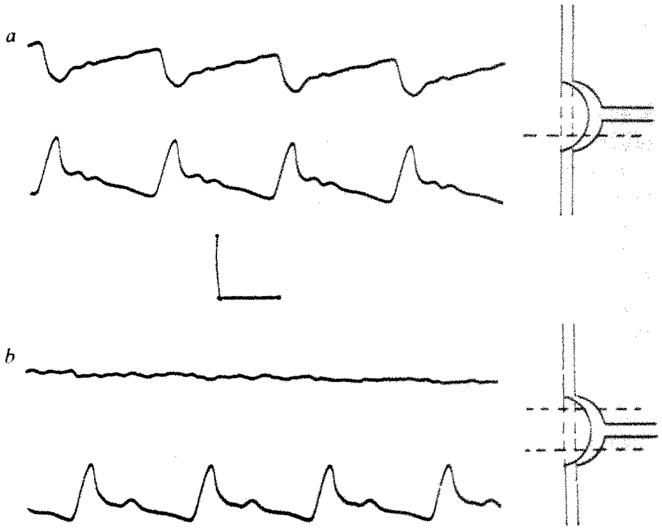

Fig. 3 Simultaneous recording of tension (upper) and pressure (lower) from the *in vivo* rabbit aorta. In (*a*), the distal side of the bypassed segment was severed from the intact aorta; in (*b*), the proximal side was then cut. Scale bar: 0.3 g, 40 mm, 150 ms; basal blood pressure in both (*a*) and (*b*) is 85 mm.

same velocity as the pulse pressure waves. The resulting synchrony between the pulse and contraction waves ensures that the aorta relaxes as pulse pressure increases and contracts during pulse pressure diastole.

The physiological function of the aortic oscillations remains a topic for conjecture. A previous study[17] has suggested that the aortic arch may undergo a contraction–relaxation cycle with a 1:1 correspondence with the heartbeat, possibly aiding in the diastolic propulsion of blood. Another role may be to reduce mechanical stress on the aortic wall. Prokop *et al.*[18] showed that the rate of change of blood pressure, but not its absolute magnitude, is the primary cause of aortic rupture. Thus, the observed relaxation during the increase in pulse pressure may locally reduce the rate of change of blood pressure and protect the aortic wall from mechanical damage.

No need for a new membrane model

Fritz Jähnig

Max-Planck-Institut für Biologie, Correnssstrasse 38,
74 Tübingen, FRG

Schindler *et al.*[1] recently reported lateral diffusion measurements in reconstituted membranes of phospholipid (PL), lipopolysaccharide (LPS) and *Escherichia coli* matrix protein (P), using the technique of fluorescence recovery after photobleaching (FRAP). Evaluation of their data led Schindler *et al.* to conclude that the fluid mosaic model is an inadequate description of the membrane and to propose a new membrane model. Their conclusion was based on identifying the fluid mosaic model with a particular binding behaviour of LPS to matrix protein. I present here a more general model for the association of membrane components, and demonstrate the use of lateral diffusion data in elucidating membrane structure. The data of Schindler *et al.* are shown to be reasonably interpretable on the basis of an association of LPS and matrix protein, which obviates the necessity for postulating a new membrane model.

I begin with a discussion of the lateral diffusion in a mixed membrane observed by the FRAP technique. Schindler *et al.*[1] studied the lateral diffusion constant D_S of one component such as LPS or PL, termed substrate, at different protein concentrations. The substrate molecules may be subdivided into those which are bound to protein and do not exchange in the time scale of a FRAP measurement, and the rest. D_S is given by the contributions from the non-exchanging molecules of molar fraction n_{nonex} and the remainder of the molar fraction n_{ex}: $D_S = D_P\, n_{\text{nonex}} + D_{\text{ex}}\, n_{\text{ex}}$. The diffusion constant of the non-exchanging molecules equals the protein diffusion constant D_P, which is usually much smaller than the diffusion constant of LPS or PL. If D_P vanishes, the fraction n_{nonex} of the substrate molecules does not diffuse, and the fluorescence recovery r is $<100\%$ and given by $r = n_{\text{ex}}$. In the measurements of Schindler *et al.*[1] the PL recovery was 100% and the LPS recovery >75%, implying that some LPS molecules were fixed to matrix protein and that the matrix protein diffusion was negligibly small. D_P was indeed found to be $<10^{-12}\ \text{cm}^2\,\text{s}^{-1}$. In my treatment I will assume for simplicity that non-exchanging molecules do not exist: $n_{\text{nonex}} = 0$ and $n_{\text{ex}} = 1$, so that $D_S = D_{\text{ex}}$.

The molecules denoted as exchanging may diffuse completely freely or may interact with proteins. In the latter case, they may bind to proteins and thus become immobilized for some time, but then exchange with free molecules. Assuming the exchange to be rapid on the time scale of a FRAP experiment ($t > 1$ s), the diffusion constant D_{ex}, which is the temporal average over the free and bound states of a molecule, equals an ensemble average over the exchanging molecules at any time: $D_{\text{ex}} = D_f n_f + D_P n_b$. Here D_f is the diffusion constant for free diffusion, and the diffusion constant of the bound molecules is again equal to the protein diffusion constant D_P; n_f and n_b are the molar fractions of free and bound molecules with $n_f + n_b = 1$. I assume $D_P = 0$. Furthermore, D_f is regarded as independent of protein concentration, which is valid only if proteins do not affect the viscosity of the free-substrate phase. I introduce a normalized diffusion constant $\tilde{D}_S(\text{P}) = D_S(\text{P})/D_S(0)$, which is then simply given by the concentration of free substrate:

$$\tilde{D}_S(\text{P}) = n_f(\text{P}) \qquad (1)$$

The function $n_f(\text{P})$, a static quantity reflecting association of substrate and protein, can be derived from the law of mass action. We assume a simple binding equilibrium $\text{S} + \text{P}' \rightleftarrows \text{SP}'$, where P' denotes protein-binding sites. The dissociation constant K_d is thus

$$K_d = \frac{\text{S}_f \text{P}'_f}{\text{S}_b} \qquad (2)$$

The concentration of free binding sites is given by $\text{P}'_f = \text{P}'_{\text{tot}} - \text{S}_b$, where P'_{tot} is the total concentration of binding sites. The latter equals $b\text{P}$, with b representing the number of binding sites per protein molecule. Equation (2) can be transformed into

$$\text{S}_b = b\text{P}\, \frac{\text{S}_f}{K_d + \text{S}_f} \qquad (3)$$

Insertion of $\text{S}_b = \text{S} - \text{S}_f$, where S is the total substrate concentration, produces a quadratic equation for S_f which can be solved to yield the following expression for $n_f = \text{S}_f/\text{S}$:

$$n_f = \tfrac{1}{2}(1 - b\text{P}/\text{S} - K_d/\text{S})\left(1 \pm \left[1 + \frac{4K_d/\text{S}}{(1 - b\text{P}/\text{S} - K_d/\text{S})^2}\right]^{1/2}\right) \qquad (4)$$

The sign has to be chosen so that $n_f \geq 0$. Note that n_f depends on the protein concentration via the molar ratio P/S, which will therefore be used as the measure of protein concentration. Equations (1) and (4) represent the variation of the lateral diffusion of LPS or PL with protein concentration.

To resolve further this result we discuss two limiting cases: first, the case of small protein concentration $b\text{P}/\text{S} \ll 1$. Here equation (4) becomes

$$n_f = 1 - \frac{b\text{P}}{\text{S}}\, \frac{\text{S}}{K_d + \text{S}} \qquad (5)$$

which is a functional relationship well known from enzyme kinetics. It describes the saturation of a few protein-binding sites with substrate where the number of bound molecules is proportional to the protein concentration. This implies that the substrate diffusion constant $\tilde{D}_S$ decreases linearly with protein

0028-0836/81/080694—03$01.00

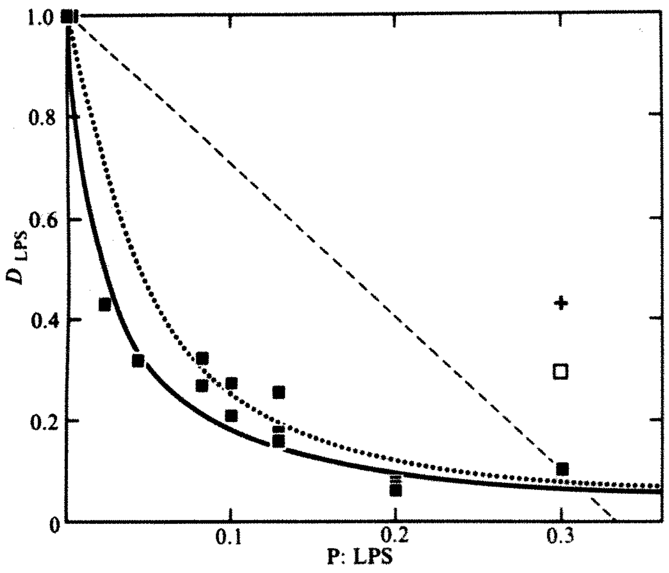

Fig. 1 Normalized lateral diffusion coefficient $\tilde{D}_{\rm LPS}$ of LPS in membranes of PL, LPS and matrix protein as a function of the molar ratio P/LPS. Experimental data of Schindler *et al.*[1] for molar ratios PL/LPS of 6 (■) and 72 (□); for the conversion of weight % protein and weight ratio PL/LPS (given by Schindler *et al.*[1]) into molar ratios, the molecular weights $\mathrm{MW_P} = 36{,}000$, $\mathrm{MW_{LPS}} = 3{,}600$ and $\mathrm{MW_{PL}} = 600$ were used. Theoretical curves are shown for PL/LPS = 6 in the limit of high P, equation (6), with $\kappa b = 325$ (—); in the general case, equation (4), with $\kappa b = 325$ and $b = 21$ (···); and in the limit of low P, equation (5), with $K_{\rm d} = 0$ and $b = 3$ (---); and a theoretical point for PL/LPS = 72 in the limit of high P with $\kappa b = 325$(+).

concentration at constant substrate concentration. The second limiting case is that of high protein concentration $b\mathrm{P/S} \gg 1$, where equation (4) yields

$$n_{\rm f} = \frac{K_{\rm d}}{K_{\rm d} + b\mathrm{P}} \tag{6}$$

This describes the situation where an excess of protein binds the few substrate molecules, but only succeeds in binding all of them asymptotically at infinite protein concentration. In this case there is saturation of the few substrate molecules by protein, which is the opposite of the first case. Here the substrate diffusion constant $\tilde{D}_{\rm S}$ shows an asymptotic decrease to zero with increasing protein concentration.

Thus in this simple binding model there is a linear decrease in the substrate diffusion constant at low protein concentration, due to protein saturation, and a gradual decrease to zero at high protein concentration, due to substrate saturation. Experimental results for $\tilde{D}_{\rm S}$ can be evaluated to yield the number b of protein-binding sites and the dissociation constant $K_{\rm d}$.

The variation of $\tilde{D}_{\rm S}$ with protein and substrate concentration derived above can also be formulated in another model which includes a partition coefficient. Two possible advantages of such a model are: first, it may be more appropriate in the case of many protein binding sites, $b \gg 1$; second, it may lend itself to further generalization concerning interactions between substrate and membrane components other than protein. Consider the partitioning of a substrate molecule between protein and lipid consisting of PL and LPS: the probability $p_{\rm P}$ that a substrate molecule is bound to protein is proportional to the concentration of free protein-binding sites (P′), and the probability $p_{\rm L}$ of association with lipid is proportional to the concentration of free lipid sites (L), so that

$$\frac{p_{\rm P}}{p_{\rm L}} = \frac{\mathrm{P}'_{\rm tot} - \mathrm{P}'_b}{\mathrm{L}_{\rm tot} - \mathrm{L}_b} \cdot \kappa \tag{7}$$

where κ is the partition coefficient. The substrate molecules in the lipid phase have been denoted free, therefore $p_{\rm P}/p_{\rm L} = \mathrm{S}_b/\mathrm{S}_{\rm f}$ at equilibrium. On the right-hand side of equation (7) we can assume $\mathrm{L_{tot}} \gg \mathrm{L}_b$, and substitute $b\mathrm{P}$ for $\mathrm{P}'_{\rm tot}$ and S_b for P'_b. Solving for S_b we obtain a relation which is identical to equation (3) and has the same solution equation (4), with the substitution

$$K_{\rm d} = \mathrm{L_{tot}}/\kappa \tag{8}$$

Thus the partition coefficient model leads back to the binding model. However, due to the appearance of the lipid-binding sites, $\mathrm{L_{tot}}$, the partition coefficient model can also account explictly for the interaction of substrate, for example LPS, with PL and LPS. The simplest approximation is

$$\mathrm{L_{tot}} = \mathrm{PL} + \mathrm{LPS} \tag{9}$$

The final result for $\tilde{D}_{\rm S}$ is obtained in the form of equation (4) for $n_{\rm f}$ with the substitution of $K_{\rm d}$ according to equations (8) and (9). In the limiting case of high protein concentration as in equation (6), the following is obtained:

$$\tilde{D}_{\rm S}\left(\frac{\mathrm{P}}{\mathrm{LPS}}, \frac{\mathrm{PL}}{\mathrm{LPS}}\right) = 1\Big/\left(1 + \frac{\kappa b}{1 + \mathrm{PL/LPS}}\,\frac{\mathrm{P}}{\mathrm{LPS}}\right) \tag{10}$$

These theoretical results can now be used to evaluate the experimental data of Schindler *et al.*[1] for the lateral diffusion of LPS. They are presented as $\tilde{D}_{\rm LPS}$ (P/LPS) in Fig. 1. The data points for PL/LPS = 6 show a gradual decrease to zero with increasing protein concentration indicating the limiting case of high protein concentration. To test this suggestion we plotted $\tilde{D}^{-1}_{\rm LPS}$ against P/LPS (see Fig. 2) which should yield a straight line according to equation (10). Although the data points scatter appreciably, they can be regarded as conforming to a straight line; a least-squares fit gives $\kappa b = 325$. There is no indication of a cross-over of the experimental points from the limit of high protein concentration to the case of low protein concentration, equation (5); therefore the quantitites b and κ (or $K_{\rm d}$) cannot be determined separately. A lower limit for b may be estimated from the condition of high protein concentration, $b\mathrm{P/LPS} \gg 1$. Assuming that this condition conforms to the experimental point at P/LPS = 0.047 in Fig. 2, we obtain $b \gg 21$. The theoretical curve for $\tilde{D}_{\rm LPS}$ with $b = 21$, derived from the general

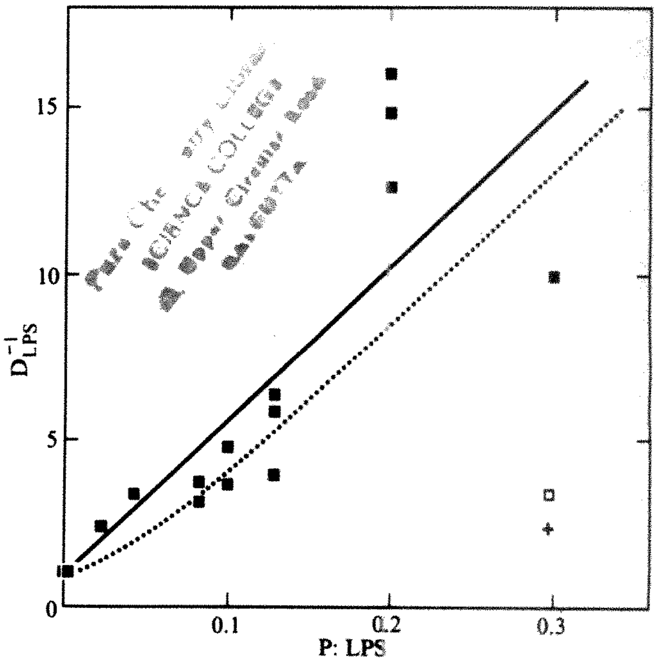

Fig. 2 Inverse of the normalized lateral diffusion coefficient $\tilde{D}_{\rm LPS}$. Representation of points and lines as in Fig. 1.

expression (4), is included in Figs 1 and 2. Comparison with the earlier fit based on equation (10), which may be regarded as the limiting case for large b, shows that $b = 21$ represents a lower limit for b. Such a high number of binding sites does not seem unlikely because such binding is only a loose association between LPS and protein, comparable with lipid–protein association, where even higher numbers of boundary lipids associated with protein are known.

In contrast to the evaluation presented here, Schindler *et al.*[1] restricted themselves to $b = 3$ and $K_d = 0$. With these values equation (6) yields $\tilde{D}_{LPS} = n_f = 0$ at high protein concentration, and at low protein concentration equation (5) yields a straight line for $\tilde{D}_{LPS}$ (P/LPS). The latter is included in Fig. 1, showing its serious disagreement with the experimental data, which led Schindler *et al.*[1] to propose a new membrane model. They adopted the number of three binding sites from studies of the *E. coli* outer membrane, where it was found that three LPS molecules are associated with one matrix protein[2]. However, the assumption $b = 3$ would imply that the matrix proteins are saturated with LPS at the relatively high protein concentration of the outer membrane, which seems rather unlikely. Within our evaluation we would predict from equation (10), with $\kappa b = 325$ and the outer membrane molar ratios $P/LPS = 1/3$ and $PL/LPS = 6$, that $n_f = 0.06$, or 2.82 LPS molecules are associated with 1 matrix protein. This number for the site occupation agrees well with the experimental result, while the number of binding sites is expected to be much higher, as discussed. Note, however, that the evaluation of Schindler *et al.* and the one presented here differ not only in the number of binding sites, but also in the binding constant, producing a different dependence of $\tilde{D}_{LPS}$ on protein concentration.

Because the evaluation of Schindler *et al.* is too restricted, their conclusions concerning old and new membrane models are invalid. However, I hope I have made it clear that lateral diffusion measurements such as those of Schindler *et al.* are useful in studying the association behaviour of membrane constituents.

I thank many of my colleagues for stimulating discussions.

Some comments are in order to put Dr Jähnig's re-evaluation of our data in a proper perspective. We determined the lateral diffusion coefficients of lipopolysaccharide (LPS), phospholipid (PL) and *Escherichia coli* matrix porin protein in reconstituted multibilayer membranes[1], using the technique of fluorescence redistribution after photobleaching. We compared the results from a series of samples of constant relative LPS and PL content (1:1 by weight), but different protein content (0–60% by weight). It was found that as the protein concentration increased, the diffusion coefficient of LPS decreased by an order of magnitude, whereas that of PL decreased to a much smaller extent. The protein molecules at the higher concentrations were essentially 'immobile', with little or no redistribution observable over the distance scale (~3 μm) and maximum time scale (~3 × 10^3 s) of these experiments. This immobility would be a surprising result in the context of the fluid mosaic model, but is not unexpected in view of considerable evidence demonstrating the self-association of porin trimers into ordered aggregates *in vivo* as well as *in vitro*[2].

Jähnig has chosen to interpret these results solely in terms of specific LPS binding to the immobile protein, leaving both the dissociation constant and the stoichiometry of binding as floating parameters. This analysis can yield results consistent with the data, but only if one allows a total of at least 21 LPS binding sites per protein monomer (that is, ~63 sites per trimer).

In contrast to the above, we[1] did not assume that in the absence of specific binding the diffusion rates would be necessarily unaffected by the presence of an immobile protein matrix in the membrane, but set out to try to determine what other factor, if any, could be contributing to the observed diffusion characteristics. We evaluated the possible effect of LPS binding consistent with that which we considered to be the best available value of binding stoichiometry. Based on evidence of copurification, we estimate this as 9 LPS molecules per protein trimer[3,4]. Under this constraint, the binding model of diffusion could not account for the magnitude of the observed decrease in LPS diffusion. As a possible explanation of this difference we speculated that the translational diffusion of membrane components in these conditions might bear a closer resemblance to diffusion through a polymeric network than to diffusion in a simple viscous fluid. The differential effects observed for LPS and PL would be explained by the different sizes of the diffusing species. The part of the polymeric network in this scenario is played by the immobile protein matrix. Subsequent experiments[5] have suggested that the peripheral protein matrix of erythrocyte membranes may exert a similar control over the diffusion of integral membrane proteins projecting beyond the membrane bilayer.

Evidence is not yet available to allow a final definitive analysis. The value of the stoichiometry we have selected is, admittedly, a relatively soft number—it could be higher. At the same time, the value deduced by Jähnig seems unreasonably high for a specific binding interaction. The truth probably lies somewhere in between.

Epidemiological and immunological evidence indicates that the K1 capsular polysaccharide confers the property of virulence on *Escherichia coli*. *E. coli* K1 is associated with invasive diseases in humans and in laboratory and domesticated animals[1]. K1 isolates account for 80% of *E. coli* neonatal meningitis and comprise the majority of capsular types in neonatal septicaemia without meningitis and in childhood pyelonephritis[2,3]. Passive administration of K1 antibodies prevented bacteraemia and meningitis in infant rats fed *E. coli* K1[4]. Nonencapsulated

§ Present address: Bethesda Research Laboratories, Rockville, Maryland 20850.

derivatives of these invasive K1 strains did not cause bacteraemia in infant rats, although intestinal colonization was similar to that of the parent strains (M. Achtman and R.P.S., unpublished results). Several reports propose that the *E. coli* K1 capsular polysaccharide exerts an anti-phagocytic effect similar to that observed with other pathogenic encapsulated bacteria[5,6]. One approach to studying whether the K1 antigen is sufficient to confer virulence or if other *E. coli* structures are necessary is to isolate the K1 genes for genetic and biochemical analysis. Recombinant DNA methodology provides a powerful tool for such an approach. Here, we report the molecular cloning of the *E. coli* K1 antigen genes. The cloned K1 genes synthesize a capsule in *E. coli* K12 indistinguishable chemically and immunologically from that of wild-type K1 strains.

The K1 capsular polysaccharide is a linear homopolymer of α2–8-linked *N*-acetylneuraminic acid (NANA)[7,8]. A genetic locus, associated with K1 biosynthesis, linked to the *serA* locus on the *E. coli* chromosome and termed *kpsA*, has been described elsewhere[9]. A membrane-associated sialyltransferase complex catalyses the incorporation of sialic acid from CMP-sialic acid into polymeric products[10]. The number and function of the genes involved and the molecular events controlling the synthesis and assembly of the K1 polysaccharide have not been elucidated. Therefore, we chose to use the cosmid cloning vector pHC79 in conjunction with *in vitro* λ packaging techniques to clone the K1 genes[11,12]. The plasmid pHC79, a 6.4-kilobase derivative of pBR322, confers resistance to ampicillin (Amp) and tetracycline (Tc)[11]. *E. coli* RS218 (ref. 13) (*O*18, K1, H7) chromosomal DNA[14] (75 μg ml^{-1}), partially digested with *Bam*HI, and *Bam*HI-cleaved pHC79 (225 μg ml^{-1}), were mixed and ligated in a total volume of 20 μl (ref. 12). *Bam*HI inactivates the Tc resistance gene of pHC79. Ligated DNA (8 μl) was packaged in 400 μl of packaging lysate[12]. *E. coli* K12 strain HB101 (ref. 15) (*hsd*R, *hsd*M, RecA, *leu pro*) was transduced by diluting the packaging mix to 2.0 ml with L-broth[16](LB) (containing 200 mM $MgSO_4$) and adding the mixture to 10 ml of cells (10^9 per ml in LB grown in 0.4% maltose). After 10 min adsorption at 30 °C the mixture was diluted five-fold with LB, incubated for 1 h at 37 °C, concentrated 10-fold and plated on L-agar[16] or antiserum agar[17] containing 50 μg ml^{-1} ampicillin. Resistance to Tc was determined by growth on L-agar containing 20 μg ml^{-1} Tc. Complementation of proline auxotrophy was detected by the ability of HB101-containing hybrid plasmids to grow in minimal medium supplemented with leucine but lacking proline.

Amp-resistant transductants (4×10^4 per μg ligated *E. coli* DNA) were obtained from the L-agar plates. Thirty per cent of the transductants were Tc sensitive and 1.4% were proline prototrophs, confirming the insertion and expression of *E. coli* chromosomal DNA into the *Bam*HI site of pHC79. Amp^R colonies (6×10^3) were pooled from L-agar plates and stored at −20 °C. These cells were later grown in LB and their plasmid DNA isolated. Contour length measurements[18] of purified plasmid DNA showed a homogeneous population of 43.8 kilobases (14.78 ± 0.57 μm). This is consistent with sizes previously reported for cosmid hybrids[11].

The K1 antigen in the transduced cells was detected by halo (precipitin) formation on antiserum agar plates containing equine meningococcal group B antiserum (the K1 capsular polysaccharide is structurally and antigenically identical to the meningococcal group B polysaccharide)[8]. There were fewer Amp^R transductants per μg ligated *E. coli* DNA on antiserum agar than on L-agar and no halo-producing colonies were observed among more than 1,500 transductants. In contrast, when Amp^R cells from the L-agar colony pool were plated on antiserum agar, many halo-producing colonies were isolated. Our inability to isolate transductants containing K1, except after plating on medium lacking antiserum, may reflect a delay in the expression of the newly acquired K1 genes. *E. coli* K12 was sensitive to the bactericidal effects of the antiserum; Table 1 shows a 10^5-fold decrease in plating efficiency of HB101 on antiserum agar. The bactericidal effect was eliminated by heating the serum at 56 °C for 30 min, suggesting that serum sensitivity was due to complement proteins. *E. coli* K12 expressing the K1 antigen was not serum sensitive (Table 1). This is probably due to shielding effects of the capsule on deeper cell structures capable of activating complement proteins.

Another factor contributing to the difficulty in isolating K1 transductants was the instability of pHC79/K1 hybrid plasmids. We observed a 10^4-fold decrease in the number of K1$^+$Amp^R organisms following overnight growth in the absence of antibiotic selection. The instability of the plasmid is consistent with previous observations. Henning *et al.*[19] failed to find the *OmpA* gene in the *E. coli* hybrid gene bank of Clark and Carbon[20]. Nishimira *et al.*[21] also failed to find complementation of other outer membrane protein mutants in the Clark and Carbon[20] collection including the *OmpC* and lipoprotein genes. Henning *et al.*[19] were unable to clone the *OmpA* gene on a multicopy vector; *OmpA* was cloned on λ and pSC101 vectors. These data suggest that the gene dosage of outer membrane proteins and other surface structures, generated by cloning on multicopy

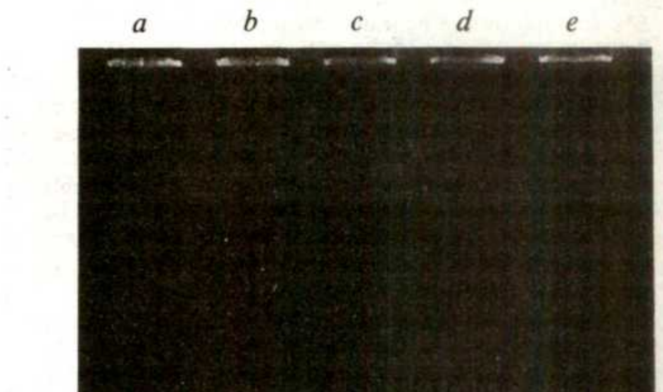

Fig. 1 Electrophoresis in 0.7% agarose gel of *Bam*HI-digested plasmids. Plasmid DNA was isolated as described elsewhere[13] and treated with endonuclease *Bam*HI in 100 mM Tris-HCl (*p*H 7.5), 10 mM $MgCl_2$ and 50 mM NaCl at 37 °C for 1 h. Samples were run in 0.7% agarose gels, Tris-borate buffer, *p*H 8.2, for 3 h at 120 V. DNA fragments were visualized by staining with ethidium bromide (0.4 μg ml^{-1}) and photographed in short-wavelength UV light. Molecular size standards of *Eco*RI-cleaved λ DNA were used to indicate fragment length. Lane *a*, pHC79; lane *b*, pSR23; lane *c*, pSR25; lane *d*, pSR26; lane *e*, pSR27. pSR25–27 were isolated following *Bam*HI digestion of pSR23, re-ligation[12] and transformation[22] of HB101. kb, Kilobases.

plasmid vectors, may be directly related to the lethality of the cell[19]. A recent observation that a strain in which the K1 genes have been transposed to a low copy number plasmid (F*lac*Mu) stably produced the K1 antigen is consistent with this view (R.P.S., unpublished observation).

The production of the K1 antigen could be maintained in broth cultures or on agar plates containing 500 or 100 μg ml^{-1} ampicillin, respectively. A 40-kilobase (13.7 ± 0.48 μm) plasmid, designated pSR23, was isolated from HB101Kl$^+$ cells. A *Bam*HI digest of pSR23 generated four fragments: the 6.4 vector and three *E. coli* fragments of 23, 6.6 and 5.0 kilobases (Fig. 1). A DNA–DNA heteroduplex between pHC79 and pSR23 confirmed the presence of a 35-kilobase insert in pHC79 (Fig. 2). HB101 was readily transformed[22] to ampicillin resistance by pSR23; all Amp^R transformants produced the K1 antigen. The efficiency of plating of K1 specific phage[23] was the same on HB101(pSR23) as on RS218. The 35-kilobase cloned *E. coli* fragment represents about 1 min of the *E. coli* genetic map[24]. It contains information to code for about 50 proteins and is larger than that required for K1 biosynthesis alone. Other *E. coli* genes on the hybrid plasmid have not been identified. Subclones containing pHC79 and each of the *Bam*HI fragments of pSR23 (Fig. 1, lanes *c–e*) did not produce K1 polysaccharide as determined by halo formation on antiserum agar and K1 phage sensitivity. Cells harbouring pSR27, which contains the largest *Bam*HI fragment (Fig. 1, lane *e*), synthesized NANA and had sialyltransferase activity (W.F.V. and R.P.S., unpublished results).

The structure of the K1 polysaccharide isolated from HB101(pSR23) was studied by several techniques[25]. We found that: (1) it was composed of 88% sialic acid; (2) the molecular size, determined by gel filtration, was similar ($k_d = 0.5$) to that of K1 polysaccharides isolated from other K1 strains; (3) the purified polysaccharide was negatively charged at neutral *p*H; (4) in double immunodiffusion a line of identity was observed between the polysaccharide from HB101(pSR23) and wild-type K1; and (5) the ^{13}C-NMR spectrum of the HB101(pSR23) polysaccharide was identical to that of wild-type K1.

Isolation of the K1 genes will permit a direct examination of whether the K1 capsular polysaccharide alone confers the property of invasiveness to *E. coli*. Our preliminary experiments indicate that *E. coli* K12 strains with the K1 capsular polysaccharide genes are not invasive for the infant rat. Thus, it is likely that biochemical traits in addition to the K1 capsule are required for the invasiveness of *E. coli*. The techniques of molecular biology and bacterial genetics should provide useful approaches to characterizing these pathogenic traits.

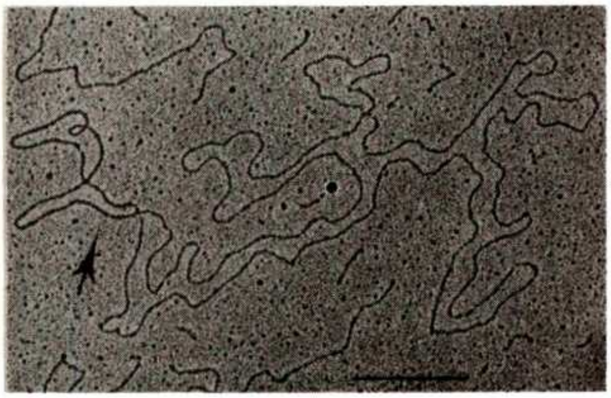

Fig. 2 Electron micrograph of DNA–DNA heteroduplex between pHC79 and pSR23. pHC79 was digested with endonuclease *Pst*I at 37 °C in 20 mM Tris-HCl (*p*H 7.5), 10 mM $MgCl_2$, 50 mM $(NH_4)_2SO_4$ generating linear molecules. pSR23 was incubated with pancreatic DNase I (0.02 units ml^{-1}) for 25 min at 25 °C, conditions producing approximately one nick per molecule. Heteroduplex analysis was performed as described previously[18]. Arrow indicates double-stranded 6.4-kilobase pHC79. Scale bar, 1 μm.

Table 1 Growth of *Escherichia coli* on antiserum agar

Strain	Plating efficiency
RS218	1.0
HB101	10^{-5}
HB101 (serum heated 56 °C, 30 min)	1.0
CSH75*	10^{-4}–10^{-5}
CSH75K1$^+$†	0.5

Cells were grown overnight in LB at 37 °C, diluted and plated on antiserum agar and L-agar. Efficiency of plating on antiserum agar was expressed relative to growth on L-agar.

* *E. coli* K12 strain (*ara, leu, lacY, purE gal trp his, argG malA, strA, xyl, mtl, ilv, met, thi, pro*).

† Chromosomal recombinant obtained from a mating with an *E. coli* K1 Hfr donor (R.P.S. and J. Foulds, unpublished).

We thank John B. Robbins and M. Carolyn Hardegree for reviewing the manuscript, William Egan for NMR studies, John Collins for providing pHC79, B. Rowe for providing K1 specific phage, and Helen C. Coon for assistance in preparation of the packaging extract.

Erratum

In the letter 'Relative departures in July temperatures in northern Canada for the past 6,000 yr' by J. T. Andrews *et al.*, *Nature* **289,** 164–167 (1981), Figs 2 and 3 have been incorrectly numbered. Figure 2 is the graph of relative departures of average July temperatures from their means and Fig. 3 a time-series of estimated July temperatures.

MATTERS ARISING

Brown adipose tissue and diet-induced thermogenesis

IT has been proposed[1,2] that 'diet-induced thermogenesis' in brown adipose tissue enables animals to dissipate excessive intake of energy and so avoid obesity. The hypothesis is claimed to justify the view that thermogenesis is more important in regulation of energy balance than control of food intake[3], and the report by Rothwell and Stock[1] has been presented by the media (a BBC Television programme *Horizon*, 10 December 1979) as embodying an important discovery in relation to human obesity. We consider their data and arguments inadequate to support the hypothesis for the following reasons:

(1) The first paper hinges on an experiment in which one group of six rats was induced to overfeed by 'cafeteria feeding' (that is, providing a variety of tasty foods)[4,5] for 3 weeks, with a second group as controls. The amount of energy the cafeteria-fed rats stored as fat was much less than the increase in their intake of energy—this discrepancy supposedly demonstrated thermogenesis. We consider that it is hazardous to infer energy expenditure in this way (see Table 1 of ref. 1), particularly where it is the quantity of primary interest. (The paper includes in Table 2 some sample measurements of oxygen consumption as 'confirmation of lowered efficiency', but energy expenditure is too variable for short measurements to be useful in balance experiments, and the adjustment of the data for body weight complicates interpretation.) Accurate measurements of energy intake, expenditure and storage over a balance period are laborious and technically exacting; any systematic errors, however, cumulate in balance experiments, thus unless all three components of energy balance are measured there is no check on accuracy.

(2) Metabolizable energy intake (that is, the energy in food supplied minus the losses due to scattering and in excreta) cannot be reliably predicted from food composition tables or prior measurements: bomb calorimetry of the actual materials is essential. This must apply particularly to cafeteria feeding, where a variety of proprietary foods of high energy density are offered.

(3) Energy storage was determined by subtracting initial from final carcass energy values, determined by *post mortem* analysis; the method and its precision are not stated. The initial values were obtained from a group of six rats, killed at the start; their body composition was stated to be identical with that of the two groups used in the experiment, on the basis of *in vivo* tritium dilution measurements. We believe that estimation of body fat by *in vivo* body water measurement is inevitably inaccurate, and that this view is confirmed by Rothwell and Stock's data[6] on the tritium method.

(4) Rothwell and Stock[7-9] previously reported that cafeteria-fed rats showed similar resting oxygen consumption to controls and rapid increase of weight; that is, there was no evidence of thermogenesis (though it was reported to occur briefly after cafeteria feeding had ended). There are two possible explanations, other than experimental error, for these contrasting results. Rothwell and Stock[1,10] state that rats obtained from two suppliers, although of the same strain, differed in their capacity for thermogenesis and propensity to obesity. The only difference quoted in absolute terms was that energy expenditures during cafeteria feeding were 390 and 340 kJ per day. This difference, though statistically significant, is not large, and might be within the margin of error. If it is real, the selection of rats from one source rather than the other as the basis for a general theory would seem to require justification.

(5) We believe the age of the rats may provide the explanation. In Rothwell and Stock's earlier work[7-9] female rats weighed ~300 g and males 400 g and controls gained weight at 0.5–1.0 g per day, values typical of adult rats. The rats used in the later experiment[1] were described as 'adult' but their age was not stated; the control group were gaining weight at 5 g per day which is a rate typical of young, actively growing rats. Elsewhere Rothwell and Stock[2,10] describe as 'adult' rats which were 6 weeks, 10 weeks and 75 days old. Growth is costly of energy and its rate is sensitive to the supply of energy; thus it is well known that young, actively growing animals do not acquire fat readily. We believe a discrepancy between increased energy intake and fat storage, seen in young rats but not in adults, is more likely to reflect the young animals' capacity to use energy for growth than to demonstrate a new mechanism for energy dissipation. If the young animals' capacity for growth were to be regarded as a regulatory mechanism for energy balance, it would have to be made clear that it is not one available to adults. In adults, deposition of fat, although a relatively efficient process, entails dissipation as heat of about a third as much energy as is stored[11-13]; any discrepancy found in adults between excess intake and storage would have to be shown to exceed this before any possibility of a new mechanism arose.

(6) Since the work of Dawkins, Hull and others in the 1960s[15,21] it has been accepted that brown fat, controlled by noradrenergic sympathetic nerves, is an important heat-producing organ in the regulation of body temperature in infant animals of many species. Existing evidence indicates that the amount of brown fat in the body, and the heat produced in response to noradrenaline, decline with age[14-17]. The suggestion that, in animals possessing it, brown fat might be activated in response to overfeeding is an interesting one, although in young animals such a response would be expected to be antagonistic to growth. Miller and Payne[18] and Gurr *et al.*[19] have reported that diet-induced thermogenesis is conspicuous in young pigs; the pig is thought to possess no brown fat[20]. In our view, however, better evidence is required that diet-induced thermogenesis exists at all, before the question of its mechanism is worth pursuing. Extension of the suggestion to humans, and to adults, (and so relevance to human obesity) would seem doubly doubtful. The pair of IR thermograms[1] presented are certainly not adequate evidence: the effect seen after administration of ephedrine could as readily be ascribed to circulatory changes (G. A. Brown, RAF Institute of Aviation Medicine, personal communication).

Rothwell and Stock's hypothesis may still prove correct. Our point is that a novel theory which reverses previously accepted views needs substantial supportive evidence that can stand up to critical evaluation. We do not think such evidence has yet been presented.

ROTHWELL AND STOCK REPLY—We shall deal with points (1), (2) and (3) above together. Estimation of energy expenditure by the carcass balance method (that is, intake minus storage) is an accepted

0028–0836/81/080699—02$01.00

and reliable technique that has been in routine use in our laboratory for 15 years. We have introduced various improvements to increase accuracy and the coefficient of variation on carcass energy determination is less than 1% (ref. 1). A further improvement we have made is to match groups of rats at the start of the experiment (including those killed for determining initial carcass energy) on the basis of weight and body composition. In adult rats there is a poor correlation between body weight and energy content[2] and matching groups by weight alone or previous growth rate (as used by others, including Hervey and Tobin) can introduce very large errors. Obviously matching for body composition has to be done using *in vivo* measurements and, contrary to Hervey and Tobin's statement, our tritium method[3] gives values for body fat which do not differ from values determined by direct carcass analysis. However, after using the *in vivo* method for group matching, we then determine carcass composition of all groups (initial and final) by direct analysis, and this was clearly stated in our article[4].

We would share Hervey and Tobin's reservations about the use of food composition tables, but by carefully selecting appropriate foods and making meticulous measurements of food intake, metabolizable energy can be estimated conveniently and reliably. We have checked this against determinations by bomb calorimetry and the errors are small (always <5%)—this must be compared with the very large difference in energy intake (80%) on the cafeteria diet. All non-quantal measurements have errors and the skill of experimental design relies on producing differences that are not obscured by these errors. Thus, even if we take an extreme and unlikely 'worst case' example and assume the energy intake of cafeteria rats was overestimated by 10% and energy storage underestimated by 10%, we still find that cafeteria rats ate 62% more than controls. Of this additional intake, only 8% was stored and all the remainder was lost as heat—that is, as diet-induced thermogenesis (DIT).

Hervey and Tobin take us to task (point (4) above) for obtaining contrasting results in rats from different colonies, and yet they must be aware of the strain and intra-strain differences that are known to affect many aspects of metabolism (see for example, Miller[5]). Biologists cannot ignore these powerful genetic influences on metabolism, and selecting rats from different colonies is an attempt on our part to simulate in laboratory rats the wide individual variability seen in many animals, including man.

The rats used in our studies ranged from 200 to 400 g in weight (7–16 weeks of age). In terms of reproductive maturity these animals are past puberty and in anthropomorphic terms range from 'young adult' to almost 'middle-aged'. DIT can be induced at each age and to say (point (5) above) that age explains our results ignores the fact that rats of the same age can maintain weight on intakes that differ by up to 60% (ref. 6). If anything, our brown fat hypothesis might be used to explain why the incidence of obesity increases in later life when the amount and activity of brown fat is known to decline (refs 14–17 above). We cannot accept the argument that the energy cost of growth or fat deposition accounts for DIT for the following reasons. We have observed increased DIT when (i) the rate of growth is unaffected[6]; (ii) fat deposition is lower in one cafeteria group than another[7]; and (iii) when animals are hypophagic and losing body fat[4,8]. We have also calculated that the energy cost of increased fat deposition (when it occurs) accounts for less than 8% of the increased heat production[4] and even this assumes that all the fat was synthesized and none was derived from dietary sources.

We wonder why Hervey and Tobin accept the importance of brown fat in infant animals (point (6) above), for which there is no good quantitative evidence, and ignore the evidence provided by Foster and Frydman's meticulous study in cold-adapted adult rats[9]. Using their technique we provided similar quantitative evidence in cafeteria-fed rats[10] but they ignored this too, even though they are well aware of it. Our hypothesis is not intended to be exclusive and in our discussion of the pig experiments (ref. 20 above) we suggested alternative mechanisms of DIT in this animal which supposedly lacks brown fat, although it now appears that the young pig does possess some brown fat (D. L. Ingram, personal communication). The IR thermograms[4] are certainly not adequate to support a role for brown fat in adult man, but we doubt that 'circulatory changes' (personal communication, above) can explain how, after ephedrine, the temperature at the nape of the neck can rise above core temperature while other adjacent areas remain unaltered.

In terms of DIT, our work is not novel but merely confirmation of a phenomenon first observed at the turn of the century[11] and subsequently reported by many other workers (see ref. 4). Hervey and Tobin have ignored this earlier evidence and make no comment about the evidence for a thermogenic defect in genetic obesity (for example, *ob/ob* mice) perhaps because this implies a role for active thermogenesis in leanness. The only claim to novelty we can make is the suggestion that brown fat is the major effector of DIT and we see this as a positive development in an established line of inquiry and not a reversal of previously accepted views.

Matters Arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted. Neither contribution nor reply (if one is necessary) should be longer than 300 words and the briefest of replies, to the effect that a point is taken, should be considered.

TEXTBOOK SUPPLEMENT

Self-consciousness and the book for students

Students' books have at least one thing in common with fairy stories: they are written for the use of one section of the population by another. The authors of students' books are people who teach students and who pretend, sometimes accurately, to know what students need to know. Patronizing though this convention may seem, it appears to have survived even the fierce confrontation between students and teachers of the 1960s. The groups of students with ambitions then to help shape the university curriculum, often by the addition of "socially relevant" studies, seemed implicitly to accept that even though what to teach might be up for grabs, how to teach was for teachers to decide. Teachers have been more than willing to follow this prescription. In this convention, the contributors to the symposium of reviews of students' books which follows are teachers not students.

But does not this practice include a dangerous risk of circularity? If teachers write students' books, review them in journals such as *Nature* and also recommend them to their students, is there not a possibility that teachers' preconceptions of what students need will be self-justifying prophecies? At the level of the secondary school, there is ample evidence that this danger is not fanciful. Until the early 1960s, in Europe and North America, most science courses were marked by an almost ostentatious neglect of modern (or postwar) science. Now, some crusty teachers (mostly outside schools) argue, the pendulum has swung too far in the opposite direction. Students at schools learn about the relevance of DNA to human genetics before they know the first thing about the hydrogen bonds that hold these molecules together. Both the old and the new conventions about the content of science courses are indeed determined by teachers, acting as often as members of examination boards or members of curriculum study groups as in the classroom. Fortunately, the dangers are less serious at the level of the university.

The most obvious safeguard is the incoherence of the market in which the would-be authors of students' books must make their way. At some point in a teaching career, the impulse to see a successful course between hard covers, and launched on a wider world than that of the teacher's own university, seems to take hold. Publishers are willing accomplices, in normal times eager to make sure that their own portfolio of standard course books is comprehensive enough for them to offer almost everything to almost anybody (and also to keep their sales forces productively employed). Given only a modicum of independent judgement by teachers who are not themselves the authors of books, there is every reason to hope that the most intellectually successful course books will be those that sell most widely. Even when it seems that the simple influence of the market may be distorted by extraneous considerations — a textbook by a well-known author or from a distinguished institution — there is no serious reason to fear that students' teachers fail to recommend books honestly.

But is it proper that the important task of educating students should be determined in such a haphazard way? Might it not be better that university students, like those in schools, should be provided with books and other teaching materials that are the product of a self-conscious examination of students' needs. In short, should universities borrow from the schools and embark on deliberate curriculum development? In the past decade and more, this challenge has been cheerfully accepted in several places and in many fields of study. Groups of university teachers have spent their weekends hammering out a logical structure for some course of instruction, have gone back to their classrooms to try out the ideas on their students and have in the end subscribed their names to the title pages of one or more books. The result is not always the unsatisfactory compromise that might be expected. Especially when the objective is to devise a teaching course that crosses established disciplinary lines, the product of these endeavours may be stimulating and valuable. If, for example, the objective is to give the teaching of a subject a greater sense of history (a crying need in most fields, especially in mathematics), most practising subject teachers will acknowledge that they could profitably make use of help from others. To the extent that course-books are increasingly the product of several people who work together as a teaching team, some of the more obvious objectives of curriculum development are already assured. Yet formal curriculum development has inevitably hung fire outside the schools. Why should this be?

Some parts of the explanation are self-evident. Good teachers are rightly as suspicious of the all-embracing course-book as their better students are resentful of the intellectual straitjacket it represents. One essential part of a university education is to learn, mostly by hard experience, how to gather different nuggets of understanding from various sources, many of them books. The course-book is thus potentially an enemy of learning, a crutch and not a challenge. Second, those who teach in universities quite properly hold that it is their duty to teach their subjects in distinctive ways. It would be a great misfortune if this principle were eroded, for teaching is at its best a creative process.

These are sufficient reasons why a certain degree of anarchy in the production of students' books is to be welcomed. Another is that many books, originally devised as books for students, have become important components of the scientific literature. Feynman's three-volume *Lectures in Physics* has been for the past twenty years as much a challenge to his peers as to the undergraduates at the California Institute of Technology to whom the lectures were first delivered. In the same field but in a very different style, Max Born's *Atomic Physics* remains a classic of succinctness and a good read, even though the subject has been transformed in the past half century. R. H. Fowler's *Statistical Mechanics*, an enthralling graduate textbook, illustrates a different point; when amended to take more explicit account of the relationship between statistical mechanics and thermodynamics (as *Statistical Thermodynamics*, by Fowler and E. A. Guggenheim), the result was awkward and too didactic. Plainly, self-consciousness can be dangerous.

Self-consciousness is nevertheless not entirely to be outlawed. Indeed, there are many points in the undergraduate curriculum at which there is an urgent need of it. Why is it, for example, that chemists and physicists are still taught thermodynamics as if they were being taught quite different things? Why is the physics of engineering so different from physics as taught in physics departments? Why is the common ground between undergraduate organic chemistry and biochemistry so hard to find? Why are there nearly as many different kinds of "mathematics" as there are universities at which mathematics is taught? Why, throughout the undergraduate teaching of science, do teachers embark apparently independently on the design of experiments and projects, unable to profit from what has been done elsewhere? The dangers of self-consciousness notwithstanding, is it not time that university teachers wrestled more diligently with these problems?

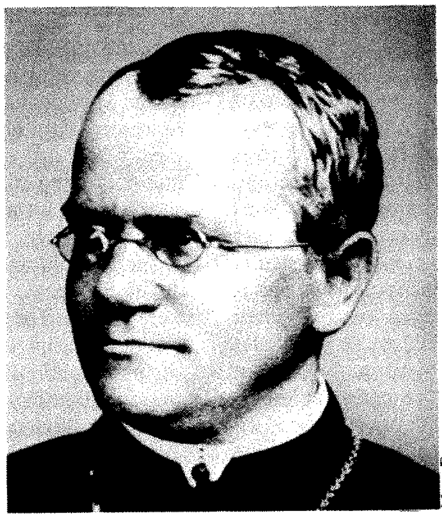
Mendel meets DNA: the teaching of genetics

D. J. Cove

Genetics. By C. J. Avers. (Van Nostrand: 1980.) *Modern Genetics.* By F. J. Ayala and J. A. Kiger Jr. (Benjamin/Cummings/Addison-Wesley: 1980.) *The Science of Genetics: An Introduction to Heredity.* 4th Edn. By G. W. Burns. (Macmillan, New York/Collier Macmillan, London: 1980.) *Principles of Genetics.* By J. W. Fristrom and P. T. Spieth. (Chiron/Blackwell Scientific: 1980.) *Biology of the Gene.* 3rd Edn. By L. Levine. (C. V. Mosby: 1980.) *Lecture Notes on Genetics.* By P. J. Russell. (Blackwell Scientific: 1980.) *Introduction to Modern Genetics.* By R. P. Wagner *et al.* (Wiley: 1980.) Further details of all books are given in the table accompanying the review.

THE publication in the past year of seven textbooks of genetics, all aimed to provide support for an introductory undergraduate genetics course, provides an opportunity not only for a comparative review of the books but also for a more general examination of how the subject should be taught at this level. The teaching of genetics poses problems both of strategy and of tactics. Strategically, a logical order of development is needed but not easy to devise. The two alternatives most commonly adopted are the classical or "Mendel before molecules" approach and the modern or "Let's start with DNA" approach. But in both of these there is the risk of compartmentalizing genetics and this risk is increased when quantitative, population and ecological genetics are considered as a third discrete topic generally tacked on behind.

The table accompanying this review indicates the gross order adopted in each of the seven texts, but the depressing point to emerge is that although some of the authors say they have opted for an historical approach (e.g. Avers; Burns) and some claim their approach to be modern and molecular (e.g. Levine; Russell), while others put forward their approach as neither historical nor modern but "born of pedagogical logic" (Fristrom and Spieth), there is rather little difference in the end product. The order of presentation is obviously different but there is little feel for the unity of the subject. Because formal, Mendelian genetics was established before biochemical genetics, we are not obliged to teach the two subjects separately; because quantitative and molecular genetics have developed largely independently of one another, the two subjects need not be kept apart for ever; and because the concept of dominance was introduced before the physiology of gene expression was understood, we are not compelled to continue to teach about dominance in an abstract and, to the student, often mysterious manner. There are of course risks in becoming a slave of the integrated approach and the sequential nature of learning inevitably imposes the need to teach some topics before, rather than alongside, others. Nor should it be forgotten that textbooks are not intended, at least in most cases, to be lecture notes for teachers. To be useful as reference works some compartmentation is desirable, but in many cases integration brings not only the advantage of reinforcing the unity of the subject of genetics but also allows some topics to be understood much more easily. The phenomenon of epistasis, for example, presents few problems to the student if introduced in the context of interaction between genes affecting the same biochemical or developmental pathway and this approach minimizes problems encountered by students in distinguishing epistasis from dominance, which are in molecular terms two quite distinct phenomena. It is interesting that Wagner *et al.*, a text which opts for the "Mendel before molecules" approach, treats epistasis in just this way, while Levine, a "Let's start with DNA" book, deals with epistasis without at the same time considering gene function. Curiously, Fristrom and Spieth, despite being a long text, fails to mention epistasis at all.



Gregor Mendel, father of modern genetics

Mary Evans

Before leaving teaching strategies, I want to return to overall order of presentation. There is no one order in which to teach elementary genetics which is superior or correct. Each teacher or textbook writer will favour his own individual approach. Some will wish to impose an evolutionary bias, others a molecular bias, some will favour a physiological and cellular emphasis, others will regard consideration of the whole organism to be more important. What is vital is to adopt a strategy which emphasizes how each field of genetics is dependent on each other field and how all are interrelated. In this respect I cannot recommend with enthusiasm any of the seven textbooks reviewed here, nor for that matter any other text published previously, although, at least in parts, Avers, Ayala and Kiger, and Wagner *et al.* make the most effort.

And so I come to tactics. It is fortunate that most students find genetics an interesting and stimulating subject since many undoubtedly find it difficult to master. Understanding the logic involved in connecting experimental observation to final deduction is a problem encountered across the whole of science but the connecting thread is especially difficult to follow in many genetical experiments. The logic involved is, however, crucial to genetics and is why the subject remains so powerful in the analysis of living systems. Teaching students to understand this logic so that they can themselves make deductions from data is one of the biggest problems facing the lecturer, who can be forgiven for being driven from time to time to the conclusion that geneticists can only be made in heaven. Here, a textbook can help the student if the relevant logic can be returned to again and again until it falls into place.

Unfortunately, the logical and rigorous way of treating a topic is not necessarily the most interesting and is certainly the most demanding. The device of giving the conclusions first and then showing how the experimental findings are consistent with these is the approach most often adopted, but this is a poor compromise, too easily deceiving the student into believing that he has understood the principles involved. The point can be illustrated by considering the use of deletion mapping to produce fine structure maps of genes. The most straightforward approach to teaching this topic and essentially that used by those of the textbooks under consideration which deal with it, is to take as a starting point an established deletion map, usually out of deference to history the rII genes of phage T4, and to show how point mutants can be located on this map within regions defined by the end points of the deletion mutants. Most students find this approach easy to follow yet, if asked to construct a deletion

---

[1] Text potential = number of pages of text × estimated maximum number of words which could be included on a full text page. [2] Estimated as the mean of 50 pages chosen at random. [3] Available separately in a "solutions manual". [4] Mitosis and meiosis introduced briefly in an introductory chapter but returned to later. [5] Not available with this binding.

map given raw data, many find the task extremely difficult. Here, a worked example might be helpful. Only Avers, Ayala and Kiger, and Fristrom and Spieth make some attempt at this but their treatments are not really adequate.

I have examined these texts more generally for their treatment of genetic logic, considering not only their approach to Mendelian genetics but also their treatment of experiments such as that of Crick and coworkers which elucidated the general nature of the genetic code and which remains an outstanding example of logical genetical deduction. On these criteria Ayala and Kiger perform best overall and genetic logic is one of Russell's stronger points. Fristrom and Spieth treat Mendelism well (but omit the Crick experiment). The other texts are more patchy; Avers acknowledges the "brilliant reasoning" of Jacob and Monod but does not attempt to duplicate it. Levine, although stressing in the preface the importance of presenting "wherever possible, the experimental procedures and data that have led to our present concepts in genetics", is the most descriptive, making little attempt to present even Mendelism in a logically rigorous way. All the texts, once again, display in their treatment of Mendelism, the extent to which they are constrained by the historical development of the subject. That Mendel was able to make his deductions concerning the mechanism of inheritance, despite the fact that the characters he used were expressed in diploid tissues and that the character differences showed complete dominance, makes him all the more to be admired. It is unnecessary however to expect students to cope with segregation, diploidy and dominance all at one bite. I favour introducing Mendelism by first considering segregation for characters expressed in haploid tissues and dealing next with a "diploid" character in which incomplete or codominance allows the immediate recognition of the 1:2:1 segregation in the F2 generation. This course is not without hazard, with students occasionally attempting to explain a pattern of inheritance in *Drosophila* by proposing that its tissues are haploid. The introduction of diploid segregation by way of incomplete dominance, however, has certainly proved satisfactory.

All the texts adopt the historical approach, in some cases appending incomplete dominance and haploid segregations as embarrassing exceptions, and in passing implying that dominance is an invariant relationship between two alleles rather than dependent on the level and aspect of the phenotype examined. Perhaps more seriously, the texts give the impression, initially, that each gene has only two alleles, one functional, the other mutant, an approach which results in the student having to backtrack when confronted with many topics introduced later. Ayala and Kiger once again perform best when these points are considered. Although describing complete dominance first, incomplete and codominance are introduced in the same paragraph, and the segregation ratios associated with them follow immediately after those obtained with complete dominance; multiple alleles are also introduced early on, but no emphasis is given to the artificiality of the concept of a unique wild-type allele.

Problem solving provides an excellent way in which the student of genetics can satisfy himself that he has understood the ideas which have been introduced to him. Surprisingly, since all seven texts are American, two contain no questions (but see table). Three contain questions but no answers, although in the case of at least Ayala and Kiger these are obtainable as a separate booklet. Burns contains both questions and answers but most of the answers are so brief as to be educationally worthless. Only Avers has, within the single book, questions together with answers which contain at least some explanation, although these are not as good as those provided by Ayala and Kiger in their solutions manual (which, rather curiously, is said in their preface to be "available to the instructor"). I see no point in including questions in a textbook unless answers, containing a clear and adequate explanation, are also readily available. Space is at a premium in all textbooks but in a genetic textbook set problems must have a high priority.

The authors of all seven books have obviously tried to make their books up to date. All contain at least some treatment of recombinant DNA technology and its implications but they do not all deal with intervening non-coding sequences in eukaryote DNA. Both Ayala and Kiger, and Fristrom and Spieth contain good if brief accounts of both these topics.

The texts vary very widely in their emphasis on figures and diagrams. Ayala and Kiger justifiably draw attention to the generous provision of illustrations in their book and must be given the prize not only for the clarity of their figures but also for general layout and design. Fristrom and Spieth is not only the most sparsely illustrated but has a layout which immediately looks dull. This is unfortunate for this textbook is certainly not dull in content. There is little to choose between the other five books with respect to design or their use of figures.

And so I come to where I am no doubt expected to name my best buy. No general textbook covering the whole of genetics can be expected to please everyone; inevitably, each will have strong and weak points. Although not perfect, Ayala and Kiger is, as I have indicated already, obviously superior on a number of counts. Despite its layout, I liked Fristrom and Spieth's treatment of many topics, including developmental genetics, and so I would make this my second choice. Of the rest, I am unsympathetic to the descriptive style of Levine, but others may be less critical; Russell, which is one of a "Lecture Notes on . . . ." series, is too superficial to be used as a reference book and does not provide as good value for money as the other books; the remaining three books all have good points — Burns, for example, emphasizes human genetics throughout, Avers integrates the genetics of discontinuous and continuous phenotypic variation, and an important point in favour of Wagner *et al.* is that I have already received favourable reports of it from my own students. However, I am disinclined to recommend any of the books except Ayala and Kiger, and Fristrom and Spieth, except perhaps for reference in libraries. □

Microbial genetics abbreviated

J.R.S. Fincham

Genetics of Microbes. By Brian W. Bainbridge. Pp.193. (Blackie/Halsted: 1980.) Hbk £16.95; pbk £7.95, $27.95.

THIS book deals with fungi as well as with bacteria and bacteriophage, and attempts to take the reader from the fundamentals up to the frontiers of research. It covers a reasonably comprehensive range of topics — some old, such as parasexual reproduction in fungi, and others rather new, including mitochondrial genetics of yeast, genetic analysis in streptomycetes, and *in vitro* manipulation and cloning of DNA in plasmid and phage vectors. The basic systems of gene exchange in bacteria, including transposons, are all described, albeit sketchily in some cases. Lambda phage gets considerable attention.

To cover all this in 170 pages (exclusive of bibliography), as Dr Bainbridge has attempted to do, is an ambitious undertaking, and I cannot say that he has been wholly successful. Conciseness is too often the enemy of clarity. Much information is presented in the form of complex diagrams, often based upon recent reviews and in themselves good and well chosen. But the captions are usually very short and often supported by only a telegraphic sentence or two in the text. Sometimes essential explanations or even facts are omitted in the rush to get on to the next topic. For example, after a brief account of gene conversion we come, a few pages later, to evidence from random meiotic products which is interpreted as favouring the idea of negative crossover interference. No hint is given that, in the light of tetrad analysis, data of this kind can be largely explained in terms of gene conversion. In the same chapter, an otherwise clear account of the Poisson distribution and its application to recombination theory is spoiled by a paragraph implying that a mean chiasma frequency of 0.5 corresponds to 50 per cent recombination (a factor of two missed here). In the chapter on the analysis of the yeast mitochondrial genome, the uninformed reader is not told that mitochondrial recombination is customarily detected and assayed in diploid hybrid clones and he will probably come away with the impression that it happens only in meiosis.

This, then, is not the ideal book, but it has its good points. The account of genetic engineering will be useful for beginners and the discussion of *Streptomyces* genetics provides information not readily available elsewhere except in the specialist literature. The chapter on DNA repair and mutation gives an accurate up-to-date account, albeit virtually confined to effects of UV. Several of the tables and figures provide good summaries of things one often wants to look up, and the bibliography is a useful guide to the primary sources. □

J.R.S. Fincham is Buchanan Professor in the Department of Genetics, University of Edinburgh.

Genes and behaviour

B. Burnet

Behavioral Genetics: A Primer. By R. Plomin, J. C. DeFries and G. E. McClearn. Pp.417. (W. H. Freeman: 1980.) Hbk £14.80, $24.95; pbk £8.10, $14.95.

BEHAVIOURAL genetics is the discipline linking the biological and behavioural sciences. It is concerned with the systematic study of the heritable bases of behaviour and the role of behaviour in evolution. The problem with teaching it is that intelligent discussion of the interesting issues depends upon a background knowledge of genetics, behaviour, statistics and evolution, and this is what the book provides. Following some historical background about Darwin and Galton, the authors discuss the theory of evolution in relation to behavioural genetics and sociobiology. There is a clear and concise introduction to genes and chromosomes and to the quantitative and population genetic approaches to the study of behaviour. Especially valuable is the careful explanation of how genetic variation in human behaviour is studied and how this yields information about the *environmentality* as well as the *heritability* of behavioural differences. They draw together the results of recent surveys which indicate that IQ differences are less heritable than earlier studies have suggested.

The authors take their material mostly from studies on human beings and small mammals except in their chapter "Mechanisms of Heredity and Behaviour", which includes bacteria, protozoa, round worms and insects. Those who, like myself, believe that invertebrates will for some time provide the arena for testing rival theories about the causal networks linking genes and behaviour may feel that advances using fruitflies and nematodes deserve more emphasis. The assertion on p.41 that "amphibians arose from the invertebrate lobe-finned fish" may discomfort vertebrate palaeontologists, and I note with interest a novel enzyme in Fig.10.1.

This is an excellent text, not only for the quality of the scientific explanations but because it deals critically with several controversial issues. It shows why behavioural genetics is intellectually exciting and practically relevant to the human situation. I recommend it for course work in the biological and behavioural sciences, and to the general scientific reader. □

B. Burnet is Reader in Animal Genetics at the University of Sheffield.

"Mini Luria"

D. H. Watson

Introduction to Modern Virology. 2nd Edn. By S.B. Primrose and N.J. Dimmock. Pp.251. (Blackwell Scientific/Halsted: 1980.) Pbk £7.50, $19.95.

IN this second edition of *Introduction to Modern Virology*, forming part of the Blackwell *Basic Microbiology* series, Dr S.B. Primrose has been joined by his colleague Dr N. J. Dimmock. The 251-page volume is amazingly comprehensive, forming a "mini Luria" in that it adopts the same general plan of Luria's *General Virology* (Wiley, 3rd Edn 1978). The treatment follows that given in a number of universities offering comprehensive virology courses as a component of undergraduate microbiology degrees.

An introductory chapter gives an historical survey of the development of ideas on the nature of viruses; a useful guide on basic techniques of animal virology is appended. Chapters on structure and nucleic acids of viruses are followed by six core chapters on the virus growth-cycle. Later chapters deal with such topics as virus pathogenicity, the immune system and interferon, vaccines and chemotherapy, and tumour viruses. A useful addition is a concluding chapter surveying virus families giving their "official" names, although the authors appear to be unaware of the recent U-turn of the relevant international committee which is dropping the unwieldy family name "herpetoviridae" in favour of "herpesviridae", after having strenuously resisted the arguments to do so in 1975!

The honours student will inevitably need to refer to more comprehensive volumes and a useful reference list is provided. Nevertheless, most teachers of virology would be more than delighted were their students to have a firm grasp of all the material in this book.

Inevitably, individual teachers will be slightly critical on one or two minor points. I was a little disappointed that the section on neutralization of viruses by antibody, reflecting the inclusion of Della Porta and Westaway in the reference section, appeared to suggest that the multiple critical site theory is fully substantiated. My preference would be to refer students to a more balanced view as represented in the reviews of Mandel. Others, perhaps, may be a little surprised at the omission of any reference to sub-unit vaccines in the relevant chapter. However a book of this size inevitably involves condensation of argument and selection of some topics at the expense of others, and there can be no serious claim of major omissions. The volume is likely to be welcomed by students and teachers alike. □

D.H. Watson is Professor of General Microbiology and Head of Department at the University of Leeds.

Spoiling the story

R. Whittenbury

Microbiology. 3rd Edn. By G. A. Wistreich and M. D. Lechtman. Pp.786 + appendices. (Glencoe, Encino, California/Collier Macmillan, London: 1980.) $20.95, £11.95.

GOOD plays, good novels, even good textbooks for undergraduates all display a common quality — a mastery of the subject, revealed in clarity of style, fluency of writing and in the skilful telling of the tale. *Microbiology,* I'm sorry to say, is not of this class. It is divided into six sections, three on basic principles of microbiology and three on related topics (immunology, medical microbiology and control of micro-organisms, and applied microbiology). Although much of the book is unexceptionable, it is badly flawed particularly in the area of basic principles.

A more personal criticism should be directed towards its "education props" style of presentation. All students (one likes to believe) relish a bit of an intellectual challenge. In this instance the challenge will, I fear, be boredom, rather than comprehension. Each chapter is prefaced by a brief description of the goodies to come and a list of major "take-home" messages, point by point, to be absorbed. In other words, the bones of the plot and the fate of the main characters are revealed before you've even had a chance to clap eyes on the chapter proper, itself subsectioned and highlighted. To reinforce this approach the chapters finish with a fairly lengthy sub-sectioned summary, again point by point — "Ribosomes are important in protein synthesis" — a list of review questions and a supplementary reading list (a bit too advanced for the readers the authors have in mind).

Excellent micrographs, black-and-white and colour photographs, and clear tables and diagrams (with one or two notable exceptions) all help to hammer home the message. One quibble I have is the pointless and irritating colour banding of the tables.

The more serious problems, emerging mainly in the basic-principle sections, stem from the remit the authors have set themselves — to write a text for students who have had some exposure to chemistry or biology, but not necessarily to both. These emerge as ill-written paragraphs and sub-sections, many errors of fact, contradictions, and over-simplification of concepts and complex issues. The last sometimes leads to incomprehensible statements or to truisms, some of which even raise spurious queries in the mind of the reader, for example "Phototrophs are noted for their photosynthetic activity". All phototrophs, of course, are photosynthetic organisms, by definition; the very form of this seemingly innocuous statement sows the seed of an idea that there may be some other and more important feature characterizing all phototrophs. Failure to integrate to ensure consistency, if not accuracy, adds to the confusion. For instance, what is written about autotrophs, photosynthesis, methane oxidizers and methane producers contains many examples of all these faults. Many of the errors (typographical included) are really inexcusable in a basic textbook.

Four final examples of the sort of thing you shouldn't find in a work of this nature are: a gross typographical error — "phoyodynnyhriv bacteria"; a fiction — that carbonates can be reduced via the cytochrome-mediated electron transport chain; a contradiction — that lignin is an exception to the rule of microbial infallibility (after giving earlier a list of bacterial and fungal species which break down lignin); a paragraph containing misinformation and needing no valedictory comment from me:

> The microorganisms in the rumen also provide other specific functions, such as the synthesis of amino acids and vitamins. Some microorganisms leave the rumen and are digested in other parts of the gastrointestinal system to serve as a major supply of proteins and vitamins for the ruminant. This is particularly important for the nutrition of ruminants because grasses are deficient in protein.

The authors have much remedial work to do before the fourth edition emerges and before the book, as a whole, can be recommended for use as a student text. Even if the text were faultless — and, potentially, it is a good example of its genre — my preference would still be for the Roger Stanier style (*General Microbiology* by R. Y. Stanier *et al.;* Prentice-Hall/Macmillan, London, 4th Edn 1977), an example of the sort of book I had in mind when writing the opening sentence. □

Nearly Fungi perfecti

Peter E. Long

Introduction to Modern Mycology. By J.W. Deacon. Pp.197. (Blackwell Scientific/Halsted: 1980.) Flexi £6.50, $18.50.
Introduction to Fungi. 2nd Edn. By John Webster. Pp.669. (Cambridge University Press: 1980.) Hbk £30, $79.50; pbk £9.95, $21.95.

MYCOLOGY, traditionally a taxonomically orientated part of a botany honours syllabus, now finds a place in microbiology courses where greater emphasis is placed on fungal development and function. *Introduction to Modern Mycology* is a welcome, though belated, addition to Blackwell's *Basic Microbiology* series, reflecting the new approach. Very much a book for beginners, it is a clearly written, compact, explanatory account of fungal structure, growth and development, coupled to consideration of the role of fungi in nature. Taxonomy and morphology are confined to the introduction and there is a concluding chapter on ways of restricting fungal growth. The 14 chapters include an amazing number of topics, aided by lengthy figure captions that impart additional information. The author admits to neglect of some traditional areas; these include the mechanisms of ascospore and basidiospore discharge, while slime moulds receive scant attention. Such omissions are largely excusable, but I draw the line at his failure to make any mention of the lichens, which number roughly a quarter of all described fungal species. The illustrations are not so well chosen as the contents and sometimes appear crude, especially in

The Great Gray Owl: Phantom of the Northern Forest, reviewed in *Nature* **288**, 519, 1980, will be published in the UK, Europe and the Middle East in March of this year by Oxford University Press. Price will be £9.95. The book is available in the USA from The Smithsonian Institution or through bookshops.

comparison with the next volume. It is a pity that the selection of further reading, mostly other books, is so restricted since it will not satisfy the interest in fungi that the book will arouse. Dr Deacon's book is currently the best, short, undergraduate introduction to fungi on the market, albeit at the cost of some oversimplification.

The second, expanded, edition of *Introduction to Fungi* is, by contrast, a reference work, suitable for second- or third-year undergraduates and of great value to all mycologists. It retains the format, style and superb standard of illustration found in its predecessor. Thus it creates the impression of a traditional mycology textbook. This is deceptive, as within its taxonomic framework lies an enormous amount of information on fungal structure, cytology, genetics, physiology and behaviour, as well as other general topics. All the subject matter is presented with precision and detail backed by innumerable references to original sources. The pre-existing chapters have been thoroughly revised, the treatment of slime moulds has been greatly extended and there are two new and welcome chapters on the general attributes of the Eumycota and on the Fungi Imperfecti. More attention than before has been paid to the production of the book, resulting in better placed and printed illustrations, a clearer hierarchy of headings, and more obvious stressing of terms through use of bold type instead of italics. In all, it is a considerable improvement on the first edition.

However, instructors who have to decide between recommending this book and the latest edition of Alexpoulos' *Introductory Mycology* (Wiley, 2nd Edn 1979) are placed in an unenviable position. Professor Webster undoubtedly provides a greater body of information about the fungi, in a work that is as helpful in the laboratory as it is in a study. Unfortunately the book is neither so easy to read nor apparently so topical as its American counterpart. This is largely a matter of presentation. *Introduction to Fungi* has only seven long chapters, necessitating numerous subheadings. In some cases it is not clear where a particular section ends. For example, "Breeding for resistance" (p.509) seems to continue into a discussion on rust life-cycles. Students will also encounter difficulties, at times, in sifting essentials from the mass of ancillary information as key points are not always well emphasized.

Any book of this length and quality, for which the author also takes on the onerous task of illustrator, carries the risk of falling just short of perfection. The present volume comes very near to escaping this fate. Despite its drawbacks for novices, it will undoubtedly and deservedly enjoy a wide market and will be regarded by many as a classic.

Peter E. Long is a Lecturer in Mycology in the Botany Department, University of Leicester.

Plant taxonomy surveyed

J.G. Vaughan

Plant Taxonomy and Biosystematics. By Clive A. Stace. Pp.279. (Edward Arnold/University Park Press: 1980.) Flexi £8.95, $29.50.

PLANT taxonomy in the modern context is very much a multidisciplinary subject and encompasses various types of botanical investigations and techniques. According to the author, this book is a broad survey of the subject and is aimed primarily at university undergraduate students and others in similar establishments. The information presented is largely limited to green plants, with the emphasis on angiosperms; fungi and lichens are excluded.

The first section deals with the scope of taxonomy and the types and development of systems of classification, the second with the sources (structure, chemistry, chromosomes, breeding systems, plant geography, ecology) of taxonomic information. The book is rounded off with discussion of the process and mechanics of classification. The treatment of the subject is thus fairly comprehensive and the text is well supported by references. Bearing in mind that the book is intended for undergraduates, I do have some minor criticisms— Fig. 3.7, showing 31 types of stomatal complex, could be daunting to such students, and the method of double-diffusion serology illustrated in Fig. 4.3 is not typical of that used by chemotaxonomists. Also, the distinction between lemon and orange on skin colour (p.225) would not be significant in West Africa, and possibly some other areas.

Stace's book is an important contribution to the literature of plant taxonomy in that it deals with all the classical and modern facets of the subject in a concise and readable fashion. Undergraduates, after a basic training in plant science, will find it most useful. Indeed, it is a valuable work for any scientist or institution seriously interested in plant variation.

J.G. Vaughan is Reader in Plant Taxonomy at Queen Elizabeth College, University of London.

Transport for botanists

James F. Sutcliffe

Transport in Plants. By U. Lüttge and N. Higinbotham. Pp.468. (Springer-Verlag: 1979.) DM58, $30.50.

RECENT research on the transport of materials in plants has been reviewed extensively in the first three volumes of a new series of the *Encyclopedia of Plant Physiology*, published by Springer-Verlag in 1975–1976. The same publishers have now issued a further book on the subject, based on Professor Lüttge's *Stofftransport der Pflanzen* (1973). It is a concise, authoritative and up-to-date account of research in a field to which the authors themselves have made important contributions.

Inevitably, in a book of moderate size covering a wide subject, some topics receive less detailed treatment than others. In general, the material reflects the research interests of the authors and so there is extensive coverage of membrane transport and its relationship to metabolism. On the other hand, phloem transport is disposed of in about ten pages and transport of water receives hardly any attention.

The first part of the book is devoted mainly to a straightforward account of various physical phenomena associated with transport processes, including osmosis, electrochemical potentials and electrogenic pumps. The Nernst equation, Goldman voltage equation and Onsager coefficients are explained. The presentation is clear and the mathematics involved should not be beyond the comprehension of a physiologically-minded biologist.

Part II is concerned with transport into cells and begins with a summary of current views on the structure of cell walls as a prelude to consideration of the concept of free space. This is followed by an account of the structure of membranes and various ideas on membrane-transport. The authors then turn to the complexities of the multicompartmented, vacuolated plant cell. Some background knowledge of cytoplasm is assumed. There is a useful appraisal of the value and limitations of the kinetic approach to the analysis of ion fluxes and an impartial assessment of the concept of dual mechanisms.

In Part III the control of transport and its relationship to metabolic processes are considered. Particular attention is paid to the role of photosynthesis in regulating ion-fluxes in algal cells and in isolated chloroplasts, and there is an interesting chapter on the influence of phytochrome and growth-regulating substances on membrane transport.

The final section of the book deals with inter-cellular and long-distance transport within plants, and covers such topics as the movement of ions across the root cortex, functioning of glands, ion-relations of stomata and transport in sieve tubes. Non-botanists will find this part of the book difficult to follow if they have no previous knowledge of plant structure and some simple line-diagrams illustrating the salient features would have been helpful.

The book is attractively produced and, in all, a useful volume. I shall recommend it enthusiastically to advanced undergraduates embarking on courses in plant physiology and to their teachers. □

James F. Sutcliffe is Professor of Plant Physiology at the University of Sussex.

World of botany

Peter D. Moore

Vegetation of the Earth (and Ecological Systems of the Geo-biosphere). 2nd Edn. By Heinrich Walter. Pp.274. (Springer-Verlag: 1979.) DM 29.40, $15.40. *Plant Geography.* 2nd Edn. By Martin C. Kellman. Pp.181. (Methuen: 1980.) Hbk £10; pbk £4.95, $10.95.

I AM sure that all ecologists and biogeographers will welcome a second edition of Heinrich Walter's *Vegetation of the Earth.* Perhaps the two most valuable features of the first English edition were its simplicity and clarity of terminology and arrangement, and its liberal use of physiological data, so well selected and integrated with climatic and distributional information. Although this new edition is slightly expanded, these two features do not appear to have been substantially strengthened. Clarity has, in my opinion, not been enhanced by the introduction of a new system of jargon. We now have eubiomes, zonobiomes, orobiomes and pedobiomes, where once we had deserts, savannahs and forests. The salt desert of Utah is now a eubiome of the pedohalobiome of zonobiome VII. Such jargon rivals terms like "dedesertification"! On the physiological side, the book remains rich in useful examples, but some omissions are conspicuous. I find it surprising that space is not found for a discussion of C_4 photosynthesis and its intriguing biogeographical implications; crassulacean acid metabolism is given only a few lines.

On the positive side, the book's expansion now permits coverage of geographic areas neglected in the first edition. This will be particularly welcomed by Australians and New Zealanders, who now receive more than passing mention — an unusual feature in any biogeography book. Overall, Heinrich Walter's book remains the best, condensed account of world vegetation on the market.

Martin Kellman's second edition of *Plant Geography* has been extensively rewritten and the material substantially reorganized. Three themes permeate the book: plant population biology, environmental history and evolution. It is a difficult task to bring together such extensive subjects at an undergraduate level and to attempt their integration. This is especially so if one feels it is necessary to start from a very basic level of biological background; within half a page he has defined and discussed mitosis, meiosis, polyploidy and introgressive hybridization. Fortunately, more resources are allocated to survivorship curves, seed demography and r and K selection. Species interactions and responses to the environment are considered, but here the accounts suffer from a lack of physiological information. The development of the interaction theme through coexistence to plant community analysis is logical, but there follows an unconformity, with chapters on techniques and then the human factor being slipped in as brief appendices.

Kellman aims in this book to stimulate in the minds of his readers questions relating to the evolution of plants and plant distributions. His careful selection of interesting topics should enable him to achieve this end, and his arrangement of material has certainly resulted in the second edition being a considerable improvement on the first. □

Peter D. Moore is Senior Lecturer in the Department of Plant Sciences, King's College, University of London.

How to stimulate students of plant physiology

L. J. Audus

Plant Hormones and Plant Development. By W. P. Jacobs. Pp.339. (Cambridge University Press: 1979.) Hbk £21.50, $16.95; pbk £7.25. *Biochemistry and Physiology of Plant Hormones.* By T. C. Moore. Pp.274. (Springer-Verlag: 1979.) DM 49, $27.

THE advent of extremely sensitive and chemospecific assay techniques has revolutionized plant hormone studies in the past two decades, and has brought into question many time-honoured theories of the hormone control of plant growth and development. What, then, do I look for in books such as these, intended as they are for undergraduate students of plant biology? Apart from a critical and balanced assessment of the present state of our understanding, I would hope to find that kind of stimulating presentation and analysis that would fire the student to go further into this fundamental science.

Of the two books under review, only Jacobs's comes anywhere near to meeting these requirements. He believes, and rightly so, that it is essential to emphasize "the development of research ideas" and this he has done quite admirably by taking carefully selected phenomena with which he himself has been most actively concerned (vascular development, hormone transport, abscission, flowering, for example), and making exhaustive, rigorous, critical yet constructive assessments based on his well-known PESIGS rules for evaluating the hormone evidence. Such treatment makes exciting reading which is marred only by occasional lapses into somewhat facetious and unnecessarily caustic criticism of other workers' deficiencies. It is, on his own admission, a very personal treatment, as witness for example the inclusion of data from his own researches in more than half of the plentiful illustrations in the text. Biochemical matters are virtually absent and the highly selective treatment leaves some important phenomena untouched (for example, geotropism) and the cover of the various hormone actions much restricted (for gibberellins only the action in flowering is adequately presented). Regrettably, ethylene is regarded as not being a hormone.

On the other hand Moore's book is predominantly biochemical, even molecular-biological. While Jacobs presents his chapters under phenomena, Moore does so under individual hormones, thus largely omitting the important matter of hormone interactions. Developmental responses are briefly covered but few (for example, dormancy) are treated satisfactorily. Detailed consideration of phytochrome, although systematic and complete, seems to be out of place in this book, especially since the role of hormones in flowering is so over-condensed and incomplete as to be dangerously misleading to the student. On the whole, hormone biochemistry is well treated; for example there is, among others, a nicely balanced appraisal of modern ideas of auxin mechanism.

While Jacobs is rigorously honest in the matter of priorities, Moore is occasionally slack; in fact his whole approach to references is puzzling. References to key researches are often not given in the lists at the end of each chapter, although these lists are much swollen by references to works which are not mentioned anywhere in the text. The student will not find this helpful.

Of the two, then, Jacobs's book would be my choice for recommendation to students, although it still falls short, in my opinion, of the earlier book by K. V. Thimann *(Hormone Action in the Whole Life of Plants;* University of Massachusetts Press, 1977) which fulfils all Jacobs's criteria concerning the development of ideas. It is just as rigorous, objective and stimulating but is better in that it maintains just about the right balance between molecular biology and developmental physiology. □

L. J. Audus is Emeritus Professor of Botany at Bedford College, University of London.

Biological "wheres"

Paul A. Colinvaux

Biogeography: An Ecological and Evolutionary Approach. 3rd Edn. By C. B. Cox and P. D. Moore. Pp.234. (Blackwell Scientific/Halsted: 1980.) £7.50, $19.95. *Biogeography.* By E. C. Pielou. Pp.351. (Wiley-Interscience: 1980.) £13.30, $31.30.

THESE are two books about the new biogeography, one a survey for undergraduates with little background, and the other a provocative series of essays touching on the state of the art.

Biogeography was the founder subject of both evolution and ecology. In Alfred Russel Wallace's *The Geographic Distribution of Animals* of 1876, evolution was triumphant and Sclater's six zoogeographic realms, each full of animals partly evolved in isolation, became evidence for evolutionary theory. The circumpolar zones of Allen, which recognized ecological realities — boreal forest, temperate forests, rain forests in rings of latitude on every continent regardless of ancestry — were ridiculed by Wallace as the study of mere adaptation. The Sclater-Wallace classification lasted until fairly recently, through to the plant geography of Good. In the intervening years, ecologists almost avoided the word "biogeography" and talked instead of life in the great formations, roughly corresponding to Allen's old zones, later to be known by Clements' unnecessary and regrettable term, biome.

But with ecology taken away, biogeography could be little more than the study of relationships towards the goal of a better phylogeny. True, a speculative fringe found excitement in continental drift and land bridges, but they made few geological converts.

For half a century, evolutionary biogeographers on an Earth of fixed continents proceeded to fill in details. At the last, Darlington in *Zoogeography* (Wiley, 1957) told us of endless radiations from the heartland of Africa (the Old World Tropics), perhaps feeling the ghostly presence of a rejected Gondwanaland.

Then came renewal. Remanent magnetism and plate tectonics gave us back Wegener's drifting continents; Pangaea and Gondwanaland lived. But even more vibrant was the incursion of ecology, as theorists of the Hutchinsonian school taught us to look at colonization, dispersal and speciation as ecological processes on a geographical scale. MacArthur and Wilson gave us *The Theory of Island Biogeography* (Princeton University Press, 1967).

Cox and Moore, in their third edition, press on with their successful look at this new biogeography through ecologists' eyes. Not only does the species equilibrium on islands stand with drifting continents as a central theme, but prime ecological concepts like Lindeman efficiency, niche and resource-partitioning find their places also. A possible worry is that ecological concepts that really require a mastery of competition theory have to be handled with the logistic hypothesis and its derivatives left out — competition is taken for granted rather than debated. Yet Cox and Moore make a brave show of giving modern ecology to students with no training in it, all the same.

Pielou's book is a survey by a master ecologist to be used by, as she puts it, "Senior undergraduates, and interested biologists and earth scientists of all kinds". She says that she is "probably rash" to attempt such a thing, but she was not. She has done what she said she would so well that no scientist of a related discipline can now be excused ignorance of the possibilities of the new biogeography.

Each of the ten chapters of Pielou's work will stand by itself as an essay, so you can really begin to read the book where you like. I recommend starting with the third, "Evolution, Phylogeny, and Geographic Spread". This sounds conventional enough; the title could be in a book from the 1930s. But you will instantly be drawn into a splendid analysis of modern systematics controversy that I just could not stop reading, even though in bed with 'flu at the time. Have you wondered what was behind the guerrilla war between Halstead and the Natural History Museum (*Nature* **288**, 208; 1980)? — read Pielou on cladistics, phylogeny and the evidence of biogeography.

She is a little hard on geologists who would not accept the biogeographic evidence for continental drift before the advent of plate tectonics — the honest truth was that it did not seem parsimonious to move a continent in order to accommodate a fossil. She puts island biogeography somewhere in the middle of the book, as a subject appealing to sectional interests, then follows that by a chapter on "Geographical Ecology". From then on the book wields the Hutchinsonian ideas of the evolutionary play in the ecological theatre, until we bow out with thoughts on the fundamental mechanisms of polyploidy and gene flow in the last chapter. It is a book both to read and refer to, highly modern but based on profound understanding of the history of an ancient subject. Many a graduate student will have both thoughts and work shaped by it. □

Paul A. Colinvaux is a Professor in the Department of Zoology at The Ohio State University.

Understanding ecosystems

I. J. Linn

Ecology: A Textbook. By H. Remmert. Pp.289. (Springer-Verlag: 1980.) Pbk DM 37, $21.90. *Ecology.* 2nd Edn. By R. E. Ricklefs. Pp.966. (Chiron/Nelson: 1979.) Hbk $22.95, £20; pbk £12.50. *Principles of Ecology.* By R. Brewer. (Holt, Rinehart & Winston/Holt Saunders: 1979.) $22.95, £10.50.

WHEN I was a student, many years ago, my early ecological diet was firmly founded in L. A. Borradaile's *Animal and its Environment* (Frowde, 1923) and A. S. Pearse's *Animal Ecology* (McGraw-Hill, 1926). Both of these books devoted much space to a detailed examination of the fascinating ways in which animals are adapted to survive in a wide range of habitats — the sort of thing which nowadays *Scientific American* does rather well. It is pleasing to note that in the new edition of Robert Ricklefs' standard work, despite some changes, he continues to open his argument with a solidly evolutionary approach to the adaptation of organisms to their physical and biotic environment. Of course he goes far beyond that — much has happened in half a century — and for me Ricklefs' *Ecology* is still the basic ecological reference book that no biologist (ecologist or not) can afford to be without. The jargon is all there; if you are not sure what is meant by "character displacement", or of the precise difference between "exploitation" and "interference" competition, the lucid explanations in text and glossary will help you out. For the numerate, there is liberal use of the necessary descriptive equations; and for those, like myself, whose command of matters mathematical is somewhat patchy, there is help in succinct English.

There are faults in the book, of course, but by and large they are minor. The major weakness is that, while the author by no means ignores work and examples from outside the Americas, his concentration on matters American (no doubt deliberate) amounts to a regrettable bias, not only for his readership outside America, but also for his domestic readers, who would benefit from broader horizons. As I scan my own bookshelves, I see that the great majority of books on ecology in English produced in the last 20 years or so are American, so it is a particular pleasure to welcome Hermann Remmert's *Ecology: A Textbook,* in which many European and some African examples are found alongside the American ones.

Remmert's book is only a third of the size of Ricklefs', so the treatment of the subject is bound to differ. Remmert has decided to concentrate on autecology, population ecology and ecosystems, and this approach is largely successful. The style of the book is also very different. You will find no jargon here, and very few equations, only plain and most readable English (the translation from the German by Dr Marguerite Biederman-Thorson is excellent). The result is a first-rate exposition of many of the basic concepts of ecology which can be read with profit by biologist and non-biologist alike. Professor Remmert is very concerned that the magnitude of the task of understanding complex ecosystems should not be underestimated, and he is sceptical of the value of mathematical models. He also has some harsh words for what he calls "ecological quacks" who offer advice on how to improve mankind's lot, and he points out that the need is to maintain in good condition the environment to which we are so well adapted, and that improvement in this context is a meaningless concept.

For this reason, presumably, he has included no section on applied ecology, unlike Richard Brewer, whose *Principles of Ecology* is otherwise similar in size and coverage, though with the expected American bias. Brewer, from his comments on Spaceship Earth, is equally concerned to conserve essentials, and his sections on the ways in which the ecologist can go about offering sensible advice seem to me not unreasonable, though I doubt if they would satisfy Professor Remmert. ☐

I. J. Linn is a Senior Lecturer in the Department of Biological Sciences of the University of Exeter.

Aquatic biology, past and future

C. M. Yonge

Fundamentals of Aquatic Ecosystems. Edited by R. S. K. Barnes and K. H. Mann. Pp.229. (Blackwell Scientific: 1980.) Flexi £7.80, $22.50. *The Ecology of Streams and Rivers. Studies in Biology,* 122. By Colin R. Townsend. Pp.68. (Edward Arnold: 1980.) Flexi £2.10.

WHEN I was on the staff of the Plymouth Laboratory the basic methods for the quantitative determination of phosphates and nitrates in the sea were being elaborated, while, at the same time, a descriptive shore ecology was being supported by experiments revealing such unsurprising facts as that organisms highest on the shore are most resistant to the effects of desiccation. Certain of us were making tentative advances in comparative physiology.

These two admirably presented and illustrated books are almost entirely concerned with the results of half-a-century of subsequent progress. The properties of the ecosystem emerge as no less significant than those of the organism or even populations of organisms. Energy flow is revealed as all-important.

The more comprehensive *Fundamentals of Aquatic Ecosystems* is the ably edited work of ten authors, each highly qualified to deal with some aspect of the subject which includes the increasing human exploitation, by aquaculture, of the products of marine and fresh waters. No better introductory survey of these highly significant aspects of modern biology could be desired, one certain to fire the imagination of senior pupils and first-year undergraduates. How rewarding, surely, to teach students already so well informed.

Relevance to the future arises out of comment in the book on the recent discovery near the Galapagos Islands of unique animal communities around submarine volcanic vents at depths below the penetration of light. Consequent description of the sulphur cycle, on which this life depends, involves mention of the industrial production of sulphur dioxide and its influence on the basic chemistry of the Earth. Such effects on the biosphere emerge as among the major hazards of coming decades.

The smaller *Ecology of Streams and Rivers* serves almost as a supplement, concerned as it is with the maintenance of populations within running waters with the constant danger of being carried seaward to destruction. It is an excellent addition to the *Studies in Biology* produced by the Institute of Biology. ☐

Sir Maurice Yonge is an Honorary Fellow in Zoology at the University of Edinburgh.

Concepts of animal behaviour

Aubrey Manning

Introduction to Ethology. By K. Immelmann. Pp.237. (Plenum: 1980.) $22.50, £14.18.

IMMELMANN defines ethology as "the study of the biology of behaviour". This covers almost everything, but whilst I am no longer convinced that ethology as a separate field exists, it remains easy to recognize the influence of the ethological *approach* in all branches of behavioural science. Certainly, we need textbooks which introduce ethological concepts, particularly as so many students are now plunged directly into elaborate sociobiological arguments and tend to give short shrift to the study of an individual's behavioural organization and development, which has always been ethology's strong point. The translation of Immelmann's book is going to be useful for it covers a lot of ground.

My heart sank at first when I saw, yet again, illustrations of Tinbergen's herring-gull bill patterns and stickleback models. Yet there are also plenty of fresh examples and it is healthy to have many from the German literature. Anyway there is nothing to say that old examples (or old concepts) are not still the best, provided that, where necessary, they are re-interpreted in the light of modern thinking. I do feel Immelmann falls short here in some cases, for example when describing the effects of the hawk-goose silhouette on game birds or when discussing terms like "action-specific energy" as causal factors in behaviour.

From a student's point of view the book is clearly set out, with sensible use of sub-headings. Systematization is taken too far in places, with Immelmann's excessive use of formal terms to classify his material. Some of these, such as "ethoendocrinology" and "acquired releasing mechanism (ARM)", are unlikely to be encountered again outside the pages of this book.

I would have liked more examples to be spelt out in detail, but Immelmann has a large field to cover and in general he summarizes very clearly. The chapter on social behaviour is particularly valuable as a modern re-statement of the ethological approach with due emphasis on sexual behaviour and care of the young. In summary, a good book to work through with students on an introductory animal behaviour course. □

Aubrey Manning is Professor of Natural History at the University of Edinburgh, where he works on and teaches animal behaviour. He is author of An Introduction to Animal Behaviour *(Edward Arnold, 3rd Edn, 1979).*

Primates in the lecture theatre

W.C. McGrew

Social Behaviour in Primates. By Neil Chalmers. Pp.256. (Edward Arnold/University Park Press: 1980.) Flexi £6.50, $19.95.

THE rise of behavioural studies of non-human primates over the past two decades has stimulated a concomitant growth of university courses, especially in North America. Because of their cross-disciplinary nature, such courses are taught in departments of anthropology, biology, and psychology, thus creating a large market for textbooks. The first wave of such books appeared in the early 1970s, Jolly's *Evolution of Primate Behavior* (Macmillan, 1972) and Rowell's *Social Behaviour of Monkeys* (Penguin, 1972), for example, but these are obsolescent.

Now comes a new entry into the area, written by an English primatologist experienced in African field-studies. The substance of the book is in six chapters — on groups, social structure, infant development, sex, dominance and adaptiveness. It focuses on fieldwork but calls in laboratory studies when appropriate, for example on hormonal effects. The approach is selective rather than encyclopaedic, and one of the author's strengths is his skill in choosing apt examples. The most serious drawback is that consideration of the function of behaviour is postponed until the final quarter of the text. What precedes is solid discussion of the causation of behaviour, but until the end there are no hooks upon which the reader can hang the obvious questions which this discussion stimulates. For example, why should primates live in groups, unlike many other mammals? Why do some, but not all, primates breed seasonally?

Still, these are but quibbles, as Chalmers has produced an admirably lucid textbook which deserves to be widely used. □

W.C. McGrew is a Lecturer in Psychology at the University of Stirling and a Visiting Faculty Member of the University of North Carolina at Charlotte.

Twelve years after the appearance of the second edition, Cambridge University Press have published a new edition of *Excursion Flora of the British Isles* by A.R. Clapham, T.G. Tutin and E.F. Warburg. The new edition is available with a plastic cover and costs £12.50.

More neuroscience

Trevor W. Robbins

Behavioral Neuroscience: An Introduction. By C. W. Cotman and J. L. McGaugh. Pp.838. (Academic: 1980.) $21.95, £13.80. *Physiological Psychology.* By T. S. Brown and P. M. Wallace. Pp.634. (Academic: 1980.) $20.95, £11.20. *Fundamentals of Human Neuropsychology.* By B. Kolb and I. Q. Whishaw. Pp.501. (W. H. Freeman: 1980.) $17.95, £8.95.

"How could anyone know enough to write a whole textbook?" Brown and Wallace thus modestly quote one of their own students in the preface to *Physiological Psychology.* Indeed, the sometimes dazzling technical advances in neuroscience have led to a proliferation in knowledge which defies the capacity of individual writers to achieve the degree of synthesis or balance required of a text. Brown and Wallace's book, however, is but one in a long line of such attempts and so it seems reasonable to consider some criteria by which textbooks in this area can be assessed.

One of my own criteria is to ask whether it is possible to guess from the relative qualities of the various sections, the specific research interests of the authors. I concluded (partly correctly) from *Physiological Psychology* that one or other of its authors had special expertise in the chemical senses, sexual motivation or circadian rhythms, since these sections seemed the most detailed and best-explained.

Most of the other topics covered fit into the familiar organization of chapters on introductory neuroanatomy and neurophysiology, sensory systems, motor systems, neural plasticity, learning and memory, and "higher processes". These subjects are generally covered adequately, but suffer from temptations seldom avoided by textbook writers in physiological psychology.

The first of these is to act essentially as an uncritical, passive reporter of what are considered to be main issues or experiments. For instance, Brown and Wallace's discussion of hunger and satiety flits uneasily between the vagaries of "central" and "peripheral" theories, for example, "But as we shall see later in this section, the pendulum is swinging back again, and is now somewhere in the middle" (p.291). Now this may be an accurate assessment of the state of that particular art but this lack of intellectual guidance would not instil me, nor I suspect, an undergraduate, with much confidence.

A second, related temptation is to avoid such shows of indecision by skirting any real discussion of the questions posed, or of the nature of the underlying processes. Thus, an otherwise tidy account of "brain stimulation reward" is marred by a meagre half-page of theoretical discussion of incentive motivation, coming almost as an afterthought. Sadly, this approach encourages the present tendency of "behavioural neuroscience" to be a subject driven by phenomena rather than by thought.

A third temptation is to litter the text with trendy material, perhaps not only to capture the excitement of contemporary research but also to make the opposition obsolete. Brown and Wallace have rightly introduced much interesting recent material, for example, on enkephalins and pain, the neurochemical substrates of learning, and, impressively, on "brain grafts". However, the "shock of the new" is not always right. What is exciting today may be reinterpreted or not even replicated, tomorrow. Although it is perhaps healthy for students to hear of controversy, it is dangerous to present it as fact. In addition, driven by the thirst for novelty, the reader expects updating in every topic, whereas Brown and Wallace's account of dopamine levels in schizophrenic brain neglects important work.

These are perhaps harsh criticisms of what is a well-produced and solid textbook. The choice and clarity of the figures is particularly good, and the writing emulates in readability that of Carlson's *Physiology of Behavior* (Allyn & Bacon: 1977), although in my opinion the latter is a more successful textbook.

In contrast to *Physiological Psychology*, Cotman and McGaugh's work represents a significant change of style in textbooks on the subject. Although much of the material overlaps with the former book, the title *Behavioral Neuroscience* emphasizes its preoccupation with neurobiology, which I found to be the strongest feature of the book.

The authors, while compiling a vast fund of useful information, have attempted to solve the problem of its critical assessment by enlisting about 20 specialist collaborators. Unfortunately, despite this expertise, the book fails to achieve that essential thematic coherence and balance in level of presentation. Some of the chapters, such as those on learning and memory are very detailed, whereas others, for example on thirst and hunger, are not. The superior colliculus is barely mentioned in the chapters "Seeing" and "Moving", and neuropsychological topics such as functions of association cortex and frontal lobe, and aphasia, are given short shrift.

The book is excellently produced with one glaring exception; the many sketches accompanying the text are poor substitutes for scientific drawings, and in a few cases, are embarrassing and superfluous.

Can there then be an ideal textbook in physiological psychology? In preparing my own courses I have found none, although many of the textbooks are very useful. If we eschew the possible unfortunate development of textbooks being written (and reviewed by) committees, then a better approach would seem to build a modular course by using books on specialist topics, such as R. Melzack's excellent and inexpensive *The Puzzle of Pain* (Penguin, 1973).

Superficial inspection of Kolb and Whishaw's *Human Neuropsychology* suggests that it will be a valuable weapon for the latter armoury, especially since it covers areas only poorly represented in the other books reviewed. I was impressed with the attempt to integrate both theory and human and animal experiments in sufficient depth to provide adequate coverage of subjects such as the neural mechanisms of language.

Although this book will be invaluable for advanced courses in physiological psychology and clinical psychology, I doubt it will be the last word on textbooks in neuropsychology. However, I also doubt that we have seen the last textbook of physiological psychology. ☐

More sight than sound

Stuart Sutherland

Perception: The World Transformed. By L. Kaufman. Pp.416. (Oxford University Press: 1979.) Hbk £10.75; pbk £6.95, $14.95. *Perception: An Applied Approach.* By W. Schiff. Pp.493. (Houghton Mifflin: 1980) $18.50, £9.95. *The Psychology of Visual Perception.* 2nd Edn. By R.N. Haber and M. Hershenson. Pp.431. (Holt, Rinehart & Winston/Holt Saunders: 1980.) $22.95, £10.50.

TWENTY years ago there was no worthwhile textbook on visual perception. This deficit was removed by the publication in 1975 of Kaufman's *Sight and Mind* and Rock's *An Introduction to Perception*, the former an advanced-level undergraduate textbook, the latter rather more elementary, but both excellent. We now have three further textbooks on vision — despite their titles, *Perception: The World Transformed* and *Perception: An Applied Approach* deal almost entirely with vision and both treat audition in a cursory and inadequate fashion.

Of the three new books, Kaufman's is the easiest to read, but is less up to date and is considerably more elementary than the other two. Haber and Hershenson's *The Psychology of Visual Perception* is exceptionally lucid and gives fair and unbiased accounts of the theories with which it deals. Schiff's text is both the least conventional and the most scholarly: as well as summarizing our current knowledge of perception, it shows how this knowledge can be applied to such problems as the design of aids for the blind and the legibility of text, and its extensive references provide the reader with ready access to the recent literature on vision.

The books have different virtues, but they all share the same fault. The mechanisms of visual perception are the way they are because they have evolved to carry out a particular task, namely, to reconstruct from the fragmentary two-dimensional data in the retinal image a three-dimensional model of the environment and to recognize the objects represented in that model. Although all the authors acknowledge that vision has a function, they fail to relate the details of the research they describe to that function. Thus, they describe the Gestalt psychologists' laws of Prägnanz (for example, the tendency to group together similar visual elements arranged in a straight line or smooth curve) without giving any indication of how the application of these laws enables the visual system to carry out its primary function.

Moreover, none of the books gives any account of the computer models that have been devised over the past decade to extract three-dimensional representations from a visual image. The attempt to construct such models has revealed the nature of the

problems that the visual system must solve, and in many instances has suggested how it actually does solve them. Not one of the books makes any reference to the work of the late David Marr, perhaps the only genius to work on the psychology of vision since Helmholtz himself. Marr's work in fact started where Helmholtz stopped: Helmholtz rightly insisted that visual perception was mediated by a series of complex inferential processes, but he was unable to specify with any rigour what these processes were. The existence of the digital computer has allowed Marr and his associates to construct computational models of the visual system that have thrown a completely new light on how it must function. Unfortunately, his work is not easy to follow and too few psychologists have grappled with it: the only good popular account is to be found in J.P. Frisby's *Seeing: Illusion, Brain and Mind*.

Two of the publishers of the three books under review have served their authors badly. In *Perception: The World Transformed* some of the figures are unnecessarily hard to interpret (e.g. p.128), others have incorrect legends (e.g. p.190), and at least one name that appears in the index does not appear on the specified page or indeed anywhere else in the text. The sins of Oxford University Press are, however, comparatively venial compared with those of Houghton Mifflin. *Perception: An Applied Approach* is the worst designed book I have ever encountered. It can be read only with extreme difficulty since each page contains three columns of text with no justification of the right-hand margins; much of the information purveyed is contained in those horrid boxes so popular with American publishers, but Houghton Mifflin have plumbed new depths of idiocy by spreading a single box over as many as five different pages, with areas of normal text and figures spattered randomly around its edges; as though these faults did not make the reader's task sufficiently difficult, the book's designer has made it almost impossible to associate the figure legends with the relevant figure, even going to the length of placing figure and legend on different and non-facing pages. The format of the book is a triumph of bad design, a nice irony given that the book's content is intended to show how a knowledge of vision can improve the design of artefacts.

In summary, then, *Perception: The World Transformed* is an excellent introduction for the novice; *The Psychology of Visual Perception* is a good but conventional treatment and is nicely complemented by *Perception: An Applied Approach*, which includes much material not normally found in undergraduate textbooks. □

Information in mind

Angus Gellatly

Cognitive Psychology. By R.L. Solso. Pp.499. (Harcourt Brace Jovanovich: 1980.) £10.95, $17.95. *Cognitive Psychology and Its Implications*. By J.R. Anderson. Pp.503. (W. H. Freeman: 1980.) £8.10, $15.

IN THE preface to his book, Robert Solso identifies two key questions raised by the information-processing approach to cognition: what are the stages through which information is processed? and in what form is information represented in the human mind? Although each of these texts addresses both questions, they differ in the emphasis given to them.

Anderson's major concern is the representation of knowledge, and much of his book is an exposition of recent models of long-term memory that employ a propositional format; indeed, he sees such models as the major achievement of modern cognitive psychology. The organization of the book reflects his commitment; peripheral stages of perception and attention are covered in a single 40-page chapter, after which interest turns to the evidence on knowledge representation. Only when his conclusions on this issue have been established does Anderson move on to apply them to the perennial problems of learning, memory, reasoning and language. By contrast, Solso's commitment is more to the methods of information-processing psychology than to a particular theoretical stance within that framework. His is the more traditional approach, starting with the detection of sensory signals and charting the flow of information into the processing system. Over 100 pages are devoted to reception and early analysis of stimuli, with consideration of memory in its varied manifestations forming the second part of the book, and higher-order cognitions the third. Both authors display an admirable familiarity with the vast literature. Anderson's clearly defined viewpoint lends his book a vigorous proselytizing air and a unity of purpose, but Solso, by allowing greater space to studies published earlier than the past decade, suggests a longer-term perspective. Anderson provides particularly good chapters on mental imagery, schemas, cognitive skills and deductive reasoning. Solso is also good on mental imagery and on attention, and he scores over Anderson by including a chapter on cognitive development.

On the debit side, the two books are open to a number of the same criticisms. Both are concerned almost exclusively with what cognitive psychologists do in the laboratory using undergraduate subjects and computers, rather than with cognition in any broader sense. Neither author makes more than passing reference to relevant neuropsychological findings, to the issues of individual and cultural differences, or to applied studies of reading. Perhaps, granted the assumptions they make, these are allowable omissions, but both authors advance staggering claims for future developments and applications of cognitive psychology that are in stark contrast to the well-worn examples of such applications that they can cite.

For teaching purposes, what are the relative merits of the two books? Solso perhaps provides the more general and easier introduction to cognitive psychology, Anderson is for the second- or third-level option course. □

Angus Gellatly is a Lecturer in Psychology at the University of Keele.

Entomological ethology

Stewart Evans

Introduction to Insect Behavior. By M. D. Atkins. Pp.237. (Macmillan, New York/Collier Macmillan, London: 1980.) Pbk $9.95, £6.50.

ALTHOUGH the value of studies in invertebrate behaviour is widely accepted, these animals still tend to be neglected in textbooks of ethology. Some general texts, such as those by Alcock (*Animal Behavior: An Evolutionary Approach;* Sinauer, 1975) and Manning (*An Introduction to Animal Behaviour;* Edward Arnold, 3rd Edn, 1979), do strike a satisfactory balance between different animal groups but others give the impression that almost all of the important research is on birds and mammals.

Clearly, students need access to a wider coverage of the behaviour of invertebrates, and Atkins's book goes a long way towards providing this for insects. In an admirably clear account, he concentrates on functional aspects of behaviour and, with well-chosen examples, illustrates both its complexity and variability. I believe that undergraduates will enjoy reading the book; they will find it informative, up-to-date and, in parts, dynamic. For instance, the chapter which includes a consideration of genetic aspects of behaviour underlines the way in which both traditional ethological techniques, such as those employed in Rothenbuhler's studies of hygienic and unhygienic honey bees, and entirely new ones, such as those involving the use of *Drosophila* mosaics, are making inroads in this area of research.

One major disappointment is, however, that the author almost totally ignores the work of insect neurophysiologists. It is difficult to understand how Huber's research, or that of several others in the same field, could be overlooked. Students ought to be aware of this work and, in my view, the book suffers from missing the opportunity to include it. This omission apart, I think that the book is good value for money. It is attractively illustrated and provides a good reading list; hopefully students will be stimulated to make extensive use of it. ☐

Stewart Evans is a Senior Lecturer in the Department of Zoology at the University of Newcastle upon Tyne.

Diversity of insects

R. W. Thorp

Entomology. By Cedric Gillott. Pp. 729. (Plenum: 1980.) Hbk £31.19, $49.50; pbk £14.18, $22.50.

THIS book is a comprehensive introductory college text for a senior undergraduate class in general entomology. It is designed to contrast with the "traditional taxonomic approach" which provides little information on insect physiology and ecology.

The 24 chapters are grouped into four major divisions: evolution and diversity; anatomy and physiology; reproduction and development; and ecology. The first of these comprises about 45% of the book, and deals with insect diversity, arthropod evolution, and classification and identification of insects, and includes a chapter on external structure. A key for the identification of all orders is provided; description of each order is followed by discussions of structure, life history and habits, and phylogeny and classification, including brief mention of the more common or important taxa. Most of the rest of the book, divisions 2 and 3, deals with structure and function of the integument, and all internal systems, and with embryonic and post-embryonic development. Finally, the author considers how insects relate to their abiotic and biotic environments, and concludes with a chapter on applied entomology entitled "Insects and Man".

The strength of the book is in the areas of physiology , developmental biology and the ecological relationships of these to abiotic environmental factors. Also, the chapters on arthropod evolution, insect diversity, classification, and identification at and above the ordinal level, especially the phylogenetic discussions, are more complete than in most single-authored texts.

Weaknesses include the lack of a discrete section on insect behaviour, and inadequate discussions of population dynamics and life tables, forest entomology, zoogeography and community ecology, thermoregulation in insects, interactive effects of abiotic factors, host specificity, economic thresholds, and methods for insect population management. The section on chemical control is poor in that possible resistance to insect growth regulators is not discussed, nor are the potential uses of anti-juvenile hormone compounds, antifeeding compounds and chemosterilants. The absence of keys and descriptions of infra-ordinal taxa reflects the author's feeling that identification is best relegated to laboratory exercises and to collections made by the students; however, this means that an additional text with keys to and descriptions of families will be needed for the lab.

It may be concluded from the author's criticism of introductory texts which are taxonomically oriented, and from my criticisms of the gaps in his coverage, that it is not easy to find a suitable text to accompany both lectures and practical work in entomology. Although most authors agree that a balanced coverage is needed, one is quickly overwhelmed by the vast amount of material to be covered in a quarter or semester. After the fundamentals of the subject have been covered, there is often little time left to introduce the fascinating diversity of natural history data available. Thus, the "balance" achieved in the introductory texts and courses currently available seems to differ according to the bias of the author or instructor. No two texts ever strike the same balance, but perhaps this is not as important as the development of student interest in this fascinating field. This new text by Dr Gillott succeeds in accomplishing this and is one of the better books available for an introductory entomology course. ☐

R. W. Thorp is Professor of Entomology at the University of California, Davis.

A new "Life" for vertebrates

Barry Cox

Vertebrate Life. By W.N. McFarland, F.H. Pough, T.J. Cade and J.B. Heiser. Pp.875. (Macmillan, New York/Collier Macmillan, London: 1979.) Hbk $29.95, £12.95; pbk £6.95.

THIS book fills a very great gap in the books that one can recommend to students. There are several adequate, sound books on the comparative morphology of vertebrates, and reference to them is certainly necessary if the student is to understand the details of the evidence of their structural and adaptive radiation. Nevertheless, with their lengthy exposition of how the hip bone is connected to the thigh bone, or of the position of the metaconule, such books provide little stimulation to the enquiring mind. Instead, they encourage the poorer student's tendency to cram facts as an alternative to the more demanding activity of trying to understand principles and to solve problems.

As the authors explain in their preface, this book is built around two themes; the evolution and the ecology of vertebrates, dealt with in a way that also integrates relevant aspects of their physiology, behaviour, locomotion or morphology. So although the list of chapter titles includes the familiar groups in the normal phylogenetic order, many other topics are either covered in separate sections within the chapters or make up independent chapters.

The book is divided into 22 chapters, half of which are by a single author (Cade or Pough), while 9 were written by McFarland and Heiser. The chapters seem uniformly to be really up to date in their approach and in the references given at the end of each. An average of only eight references per chapter is rather low, though some others are given after the illustration captions. The illustrations themselves are excellent and well chosen. Many of them have been redrawn, to provide a pleasing similarity of style thoughout the book. In some cases the authors have enlarged on a particular topic (for instance the evolution of amphibian vertebral structure) by means of a lengthy commentary-caption, so that the flow of the main text is uninterrupted.

After a brief introduction to the basic body plan of the vertebrates, the second chapter discusses their ancestry and environment of origin. The third includes very useful sections on the theory of classification and its application to vertebrates, and on species and speciation. The chapters on the different vertebrate groups deal with extinct as well as with the living groups, and with such additional topics as the origin of land vertebrates, adaptations to life in the deep sea, the ecology and physiology of dinosaurs, and the waves of extinction at the end of the Cretaceous and during the Pleistocene Ice Ages. The authors are careful to emphasize that each group possesses abilities and adaptations in its own right and that, for example, ectothermy has positive value in some ways of life rather than merely being a characteristic of groups that "failed" to become endothermal.

Five chapters scattered through the book give useful summaries of the positions of the continents and of the climatic regimes at different periods of the Earth's history. Other chapters deal with the influence that life in the water has had on basic vertebrate functions, and on the adaptations of endotherms to rigorous habitats.

In addition to being well-written and well illustrated, the paperback edition is extremely good value. It should put new life into any vertebrate course, and it thoroughly deserves to capture the bulk of the market for vertebrate textbooks. □

Barry Cox is Professor of Zoology at King's College, University of London.

Fossils the French way

John C. W. Cope

Elements of Palaeontology. By Claude Babin. Translated by N. Orriss and edited by D. Palmer. Pp.446. (Wiley: 1980.) Hbk £19, $57; pbk £7.95, $22.50.

IN HIS introduction to this book the editor mentions the important point, certainly not implicit in the title, that there is an "assumption that the reader is not a novice to palaeontological and biological terminology and technicalities". The approach therefore differs considerably from Rhona Black's *The Elements of Palaeontology* (Cambridge University Press, 1970), a book which has rapidly become the standard introductory palaeontological text.

To the British student the first part of the book will prove to be the most useful. The first chapters cover fossilization, fossil collection and preparation and the basics of palaeontological taxonomy. These are adequate treatments of the subject, but the exhortation to "gather the greatest possible number of samples" will not be welcomed by those with an eye on conservation. There follows a useful résumé of palaeoecological methods; this is well illustrated and many examples will be familiar to English-speaking students.

Part Two of the book carries the curious title "Some Facts of Evolution". After consideration of the origin of life, various aspects of fossil plants and some invertebrate fossil groups are considered. Although the treatment is claimed to be selective and not morphological or taxonomic, I find it difficult to understand why major groups such as sponges, bryozoa or gastropods are omitted whilst minor groups such as hyolithids, conulariids and tentaculitids are discussed. Treatment of major groups is often idiosyncratic. Under "Echinoderms", for instance, a short discussion of pentaradiate symmetry is followed by a presentation of the stylophoran/calcichordate controversy. There is no mention of the other 15 or so echinoderm classes — several of which could provide first-rate examples of evolutionary trends. Similarly, treatment of bivalves is restricted to their origins and their Ordovician diversification. The same approach is applied to other groups, an approach which, rather than stimulating, frustrates by its inadequacies. The final chapter in this section contains some 60 pages on aspects of vertebrate evolution, including a substantial section on hominid evolution.

The final part of the book, "Palaeontology and Evolution", briefly discusses some ideas on evolutionary theory.

The translation (from French) is acceptable but rarely more; it contains a few glaring errors (for instance that the bivalve ligament closes — instead of opens — the shell) but peculiar phraseology and word-order frequently make it awkward to read. Even with an English dictionary to hand, a few sentences are totally incomprehensible.

The good illustrations and useful reference lists cannot compensate for the sketchy and disjointed coverage in Part Two of the book, and although it contains much that is interesting, I must say that I found this book a disappointment. □

John C. W. Cope is Senior Lecturer in Geology at University College, Swansea.

Micropalaeontological survey

Alan Lord

Microfossils. By M. D. Brasier. Pp.193. (George, Allen & Unwin: 1980.) Hbk £12, $27.50; pbk £6.50, $14.95.

THE growth and development of micropalaeontology has been closely connected with interest in the world's oceans, coupled with its application to hydrocarbon exploration. The results of the *Challenger* Expedition (1873–1876) stimulated the study of small organisms and their role in modern sedimentation. Stratigraphical studies of fossil counterparts by such pioneers as T. R. Jones in Britain eventually led to the recognition in the 1920s of the use of microfossils for correlation, particularly between boreholes where drilling usually destroyed macrofossils. Since that time various groups of microfossil have been found to be useful for biostratigraphical and palaeoenvironmental purposes, usually with industry recognizing the value of particular fossils in particular situations after initial academic study. The continuing exploration of the ocean floors by D/V *Glomar Challenger* has depended on microfossils for stratigraphical control.

Dr Brasier's book provides a broad survey of microfossil groups, giving information for each on biology, hard- and soft-part morphology, ecology and distribution, relationship to sedimentation, classification and applications, together with suggestions as to further reading and hints for study. Coverage of each group tends to reflect its past importance to geologists — foraminifera, ostracods, spores and pollen, conodonts, dinoflagellates and coccoliths are given space in that order. Also included are a brief introduction, a useful appendix on techniques and a good basic bibliography. The style is economic, without a great burden of cited literature, but with many pointers to the student for further information and enough named examples to round out each chapter. Numerous line drawings illustrate the book; use of these is clearly a matter of personal preference when excellent photographs of microfossils are available nowadays.

The book is thoroughly recommended for undergraduates and junior postgraduates, not least because it complements the more detailed *Introduction to Marine Micropaleontology,* edited by B. U. Haq and A. Boersma (Elsevier, 1978). The paperback is certainly a good buy for anyone with an interest in or need to know about microfossils. □

Alan Lord is a Lecturer in Geology at University College London and teaches part of the MSc course given in the Postgraduate Unit of Micropalaeontology.

Riches of biology

E. C. Cox and R. M. May

Biological Science. 3rd Edn. By W. T. Keeton. Pp.1080 + glossary and index, pp.A51. (W. W. Norton: 1980.) $19.95, £11.50. Study guide $4.95, £2.50; teacher's manual no charge.

TEACHING introductory biology is not easy. An average class has an extraordinarily diverse set of interests, preparations, aptitudes and appetites for the subject. It is never clear, moreover, where one should start and where, or at what level, one should end, given both the richness of the subject matter and the diversity of the audience. These difficulties surface in the pages of many introductory texts, often reflecting all manner of confusions on the part of the author about pace, depth, coverage and readership. The problems are variously solved by dealing only with animals or plants; by reducing everything to a few weak bonds, permuted; by centring the discussion on the fate of mankind; or by omitting, except *en* *passant,* most of the evolution of structure and function by natural selection. Each of these narrow strategies, when vigorously pursued, can appeal to a particular audience. There is no doubt, for example, that a student already well prepared in the natural sciences can, upon arrival at a university, understand and benefit from Watson's *Molecular Biology of the Gene* or Lehninger's *Biochemistry,* two texts normally used by upperclassmen. But there are few such students. Most of us need, and some even want, a broad and responsible introduction to biology taught in a serious way at a high level. Fortunately for us, Keeton's third edition is now available.

There are many features of the new edition that set it apart from its competitors and represent improvements over the second edition. Keeton's approach has always been to begin with the rudiments of chemistry, proceed to the structure and function of macromolecules, cell structure and function, and thence on through behaviour, genetics and evolution, community ecology, the origins of life and the description of the phyla. He covers each topic thoroughly, judging the depth and breadth with care, and adding the proper notes of scholarly caution and scepticism. The book has an air of authority; too many introductory texts (and lecturers) substitute glib metaphor for real explanation (see our earlier reviews in *Nature* **284,** 106; 1980). The text consequently does not always make for a good read, but since it is aimed mainly at students in the natural sciences, and at those graduate students (and their teachers) reviewing areas outside their special competence, this cannot be faulted. No one could be expected to remember everything in this book; indeed, Keeton says in the introduction that he obviously could not remember it all himself.

The broad theme running through Keeton is that evolutionary theory accounts for adaptive strategies. It is the thread that ties together the material on the cell, energy transformation, the biology of whole organisms and, of course, genetics, evolution, behaviour and population biology. This not only gives students some feeling for the deep structure of the discipline but, as important for a beginner, supplies the outline of an image whose shape is finally supplied by what at first sight is an incoherent body of detail, often alarming in its variety.

The prose is enhanced enormously by first-rate illustrations and photographs, full colour as well as black-and-white. Many examples could be given. Two that stick in our minds are the drawings combined with electron micrographs to illustrate typical plant and animal cells with pleasing clarity, and the beautiful colour photographs of the world's major biomes and of plant pollinators in the act.

Inserts on special topics are also used; this is now a fairly standard pedagogical ploy, but it is nonetheless effective, for it allows small essays on advanced or special topics that would otherwise interrupt the text.

A list of test questions and a teacher's manual accompany the text. The former, in our view, is useful but not exceptional. The latter we can recommend, especially to lecturers who have not previously taken on an introductory course. It has several strengths, not the least being excellent advice on how to pose examination problems and on which of the areas covered in the lectures most often confuse the students.

Keeton's untimely death last year was a sad loss. This excellent text is likely to stand as a memorial for some time. ☐

Edward C. Cox is Chairman of, and Robert M. May Professor in, the Biology Department at Princeton University, where they jointly teach an introductory biology course.

Maths applied

P. T. Saunders

Statistics and Experimental Design. 2nd Edn. By G. M. Clarke. Pp.188. (Edward Arnold/University Park Press: 1980.) Flexi £6.50, $24.50. *Mathematics and Statistics for the Bio-Sciences.* By G. Easen, C. W. Coles, and G. Gettinby. Pp.578. (Ellis Horwood: 1980.) Hbk £25, $90; pbk £8.50. *Statistics for Biologists.* By D. J. Finney. Pp.165. (Chapman and Hall/Methuen: 1980.) £3.75, $9.95.

WHEN the first edition of *Statistics and Experimental Design* appeared, *Nature's* reviewer wrote that it was "clear and well written and may be strongly recommended to non-mathematical students requiring a common-sense grounding in statistical methods". I entirely agree with this judgement. The explanations are lucid, and well illustrated with examples. There are many exercises, for which model solutions are provided. The author has also added a liberal sprinkling of comments which contribute towards an understanding of the methods he is describing and which should help the reader to avoid some of the pitfalls that await the unwary user of statistics.

The contents are not much changed from the first edition. They include an introduction to probability theory, tests of significance (both parametric and non-parametric), correlation and regression, the principles of experimental design, and an account of factorial experiments including corrections for missing observations and non-normality. Students and research workers who can master the material in this not-too-large book should be well equipped to begin using statistics; those who cannot might be better advised to leave statistics alone.

Statistics for Biologists covers a similar range of material, but deals with fewer topics. This is partly because it is shorter, and partly because the author is more concerned with introducing the principles of statistics than with providing instruction in how it is used.

To some extent he succeeds, but I feel he often devotes to comment and discussion space which could more profitably have been used for techniques, even with his stated aim in mind. For example, regression occupies over four pages, yet the author neither explains the principle of least squares nor gives the formula for fitting even a straight line. Surely this must reduce the chance that the student will understand regression, if only because he cannot be given numerical examples to work out.

As an indication of the level to which students are taken, the author writes that the distinction between one- and two-tail tests is "logically rather subtle" and suggests that the reader should ask a statistician to explain it to him later on. I would have thought that this was one of the basic principles that students ought to learn; it is even hard to read many statistical tables if you don't understand this point. The problem does not arise within the book, as no full tables are provided. Students who find the author's style to their taste will profit from reading this book, but it will leave them with a lot more to learn.

If *Mathematics and Statistics for the Bio-Sciences* had been better written, it could have helped to satisfy a real need. But there are too many things wrong with it. The authors have chosen to write in a rather formal style, which they do not always handle well. I was not impressed with their explanations of such important ideas as limits and derivatives; these are difficult concepts for beginners to grasp, and require a better and more carefully worded treatment than they receive here.

The presentation is often slipshod. For example, while it is certainly true that "Two matrices **A**, **B** can only be equal to each other if they are the same size, say $m \times n$, and all their corresponding elements are equal", the authors should have made it clear that this is the *definition* of equality, and that there is not, as their statement implies, some further condition to be satisfied. It also seems odd to introduce the Poisson distribution and even calculate its mean and variance without mentioning the assumptions on which it is based and (therefore) its main application.

The one really good feature of the book is the large number of realistic biological examples and exercises. Anyone teaching mathematics to biologists will find these very useful. But I cannot recommend the book to students, either for classroom work or for individual study. ☐

P. T. Saunders is a Lecturer in Mathematics at Queen Elizabeth College, University of London.

Across the span of biophysical chemistry

Joseph E. Coleman

Biophysical Chemistry, in 3 parts. By C. R. Cantor and P. R. Schimmel. Pp.1,370. (W. H. Freeman: 1980.) Pt I hbk £17.70, $31.95; pbk £9.20, $16.95. Pt II hbk £20.70, $37.95; pbk £10.60, $19.95. Pt III hbk £22.40, $39.95; pbk £11.90, $21.95.

IT IS difficult to give a simple definition of biophysical chemistry. Scientists who have considered themselves biophysicists have covered such a wide variety of subjects, from the physics of ion transport to crystallography, that it is difficult to settle on a satisfactory definition. To avoid narrowness, it is perhaps best to define the field as that in which physical methods are applied to the study of biological systems — molecules as well as larger aggregates. To date, such an immense number of physical techniques have been used in this way that it has been difficult to find a textbook which covers even a representative number of them. At the same time, the study of these methods must be coupled to a reasonably complete understanding of the structure and function of the objects under study — in most instances biological macromolecules.

Cantor and Schimmel have chosen to attack the problem of the breadth of biophysical chemistry by producing a three-volume work of nearly 1,400 pages. The concept is admirable. The first volume, entitled *The Conformation of Biological Macromolecules,* sets the stage by discussing in detail the structures to be studied by various physical methods. Here, the authors have in fact set one of the few limits to their scope by confining the discussion for the most part to homogeneous macromolecules. While the existence of macroassemblies is mentioned in appropriate places, this limitation seems reasonable in that most of the best illustrations of the applications of biophysical chemistry come from studies of homogeneous biological macromolecules. The authors on occasion indicate the power of the methods of studying subcellular particles or even whole cells, but this aspect is not emphasized. Hence the first volume is devoted primarily to discussion of protein and nucleic acid structure, polysaccharides, lipids and membranes being given rather less space. The treatment is thorough, starting with composition and chemistry of the constituent monomers and extending to the static structure of the polymers and on to a discussion of the forces that determine protein folding and nucleic acid structure.

Having set the stage by presenting the structures to be studied, the second volume, *Techniques for the Study of Biological Structure and Function,* presents the physical techniques required to determine the macromolecular structures. Since the methods covered are those used to derive the information in the first volume, a purist might quibble about the relationship of the cart to the horse, but as a learning format such an approach has an advantage, since the context for the application of these (bio)physical methods is clear beforehand. The number of physical techniques applied to one or another biological macromolecule has become so great that it is difficult to be all-inclusive, and Vol. II is not. In a number of specific areas the presentation is extensive, as for all types of optical spectroscopy; hydrodynamic techniques are also well covered. Approximately 130 pages are devoted to X-ray crystallography, including scattering, and to a short mention of extended X-ray absorption edge spectroscopy. This is a thorough and well-presented discussion.

In the magnetic resonance section, both NMR and EPR are covered. The EPR discussion is rather brief; no examples of transition metal EPR spectra are given and the student will have difficulty in understanding even the most basic aspects of the interpretation of EPR spectra from the material given. On the other hand, the NMR section gives an excellent presentation of the theoretical and basic aspects, including relaxation mechanisms. The applications section is not as good. Most of the spectra are out of date; NMR technology has improved so much that even ^{1}H spectra from the early 1970s do not do justice to the field.

The third volume is entitled *The Behavior of Biological Macromolecules.* The idea behind this section would appear to be that since the student now knows his structure and the methods for discovering it, he can now use this information to understand some of the more complex interactions of biological molecules. These include ligand binding to macromolecules (both equilibrium and kinetic aspects), the variety of "allosteric" phenomena involved in biological regulation, and conformational equilibria found in proteins, nucleic acids and membranes. Many specific examples of the various methods dealt with in Vol. II are given in Vol. III and make the discussion of applications of biophysical techniques more complete. This last volume also covers some other methods such as differential scanning calorimetry — an important addition. The extensive ^{1}H-NMR studies of t-RNA are presented here with spectra somewhat more up to date than those appearing in the NMR section proper.

The book is sufficiently mathematical to be relatively rigorous without overdoing it. There is an appendix giving a brief review of matrix algebra, and appropriate problems are found at the end of many of the chapters, with answers in the back of each book.

Minor criticisms aside, one has to conclude that the three-volume concept of presentation was well-founded and that the execution is excellent. I believe that this will be the textbook of choice for a course in biophysical chemistry; I can think of no other text that is as complete or as consistently well done over such a broad spectrum of subjects. □

Joseph E. Coleman is Professor of Molecular Biophysics and Biochemistry at Yale University.

Biochemical quartet

David Saggerson

Biochemistry: A Case Oriented Approach. 3rd Edn. By R. Montgomery *et al.* Pp.711. (C.V. Mosby: 1980.) Pbk £11.50, $19.95. *Biological Chemistry: The Molecular Approach to Biological Systems.* By K.E. Suckling and C.J. Suckling. Pp.381. (Cambridge University Press: 1980.) Hbk £25, $59.50; pbk £9.95, $19.95. *Biochemistry and Physiology of the Cell: An Introductory Text.* 2nd Edn. By N.A. Edwards and K.A. Hassall. Pp.448. (McGraw-Hill: 1980.) Hbk £15.95, $38.20; pbk £7.95, $19. *A Guidebook to Biochemistry.* 4th Edn. By M. Yudkin and R. Offord. Pp.261. (Cambridge University Press: 1980.) Hbk £18, $53.50; pbk £6.95, $15.95.

OVER the past 10 to 15 years, many excellent biochemistry textbooks have appeared. To succeed in the face of such competition, any new book must be outstanding or have some unique and unusual features.

The general textbook by Montgomery *et al.* fits both of these criteria. As its title and the sketches of clinicians at work on its cover imply, it is aimed to serve the needs of students of medicine or other health-related subjects. Each chapter first presents a particular set of topics in much the same way as other, more conventional textbooks of biochemistry. This is then followed by discussion of various clinical conditions, questions and problems. The number and range of conditions covered in the book is impressive. The order of chapters is rather unconventional, starting with nutrition, followed by proteins and enzymes and the acid–base balance, before discussion of cellular metabolism and its regulation. It is explained that the introduction of these particular topics early in the book permits a wider range and fuller discussion of clinical cases in subsequent chapters. I cannot argue with this. The book is imaginative, full of information, well referenced (up to 1979 in some cases) and clearly set out. As someone who is personally involved with the challenge of imparting biochemical knowledge to medical students in an interesting and relevant fashion, books of this kind are most welcome. It is likely, though, that the book requires a course to be deliberately constructed around it (as the authors do at the University of Iowa College of Medicine).

The Sucklings' book falls clearly in to two parts. The first two-thirds is largely devoted to explaining in chemical mechanistic terms a wide range of biochemical reactions. Since there are few books with this approach, this is useful either to explain biochemistry to chemists or chemistry to biochemists. Each chapter contains a number of problems which are solved with brief explanation at the end of the book; however, it was not always apparent to me that the information presented was sufficient to enable a student to tackle the problems satisfactorily. The last third of the book covers a number of topics such as enzymes as catalysts, enzyme mechanisms (using kinase-catalysed reactions as examples), control of enzyme activity, biochemical techniques (separation methods and structure determination), membrane structure, drugs (design and metabolism) and communication between cells (hormones and the immune response). It is not clear why these topics have been selected for inclusion considering the nature of the earlier part of the book. This curious mixture is presented in a rather superficial way. One cannot but feel that the book would have been better if this last third had been omitted and the topics left for the general textbooks where they are better covered.

Cellular Biochemistry and Physiology by Edwards and Hassall (McGraw-Hill, 1971) has now metamorphosed into *Biochemistry and Physiology of the Cell*. This is similar in size to its predecessor, having the same objectives presented in the same style. In a modest-sized book the authors have managed to incorporate a considerable amount of material and present it in a clear and concise manner. I see this book as being a valuable introductory text for biochemistry students or as a main text for those following biochemistry as a subsidiary subject. The main areas of the subject are dealt with — protein chemistry, enzymes and their kinetics, intermediary metabolism and protein synthesis, together with specialist sections on nerve, vision and muscle contraction — and throughout the book a number of important techniques are introduced and described. I found the discussion of the control of metabolism, including hormones, which has been considerably expanded since the 1971 edition, to be particularly good. As the authors themselves say, increases in knowledge rendering a book "more advanced" may in fact make it easier to read. Incidentally, this book was the only one of the four reviewed here presenting a credible, but simple explanation of the chemiosmotic theory of oxidative phosphorylation.

The book by Yudkin and Offord is the most elementary of the four. In general it presents a superficial outline of biochemistry under the four section headings, "Structure and Function of Macromolecules", "Metabolism", "Molecular Genetics and Protein Synthesis", and "Compartmentation and Regulation". With 250 rather small pages it cannot cover the same amount of ground as Edwards and Hassall; in fact some important topics are missed out and the explanation of others is rather thin. The book also suffers from a rather dull format. I was particularly disappointed to find no discussion of any of the important techniques of biochemistry nor any simple enzyme kinetics; this latter omission makes explanation of some aspects of enzyme action difficult. I also feel that the authors' approach to intermediary metabolism would have benefited from the use of more diagrams and from an attempt to present it within a physiological framework. Metabolism is much more interesting if metabolic specialization of different tissues is explained alongside the physiological conditions which favour particular metabolic processes. ☐

Molecular cytology

John Edwards

Cell and Molecular Biology. 7th Edn. By E. D. P. De Robertis and E. M. F. De Robertis, Jr. (Holt, Rinehart & Winston/Holt Saunders: 1980.) $24.95, £10.95.

Is cell biology a discipline in its own right? What, for example, are the prospects for a biological degree course which cuts horizontally across the traditional divisions between animals, plants and microbes, as does biochemistry, but focussed at the level of the cell? Textbooks with "cell biology" in their titles often are heavily weighted towards biochemistry, usually shorn of its tougher shadings into physical and organic chemistry. Not so with this volume, evolved over more than 30 years from a text of general cytology.

The core of this substantially rewritten edition continues to treat the cytoplasmic organelles and nuclei of eukaryotic cells, bringing together ultrastructural, cell fractionation and functional investigations, and is well illustrated and usefully documented (more than a third of the references post-date the previous edition). Mainstream molecular biology (one-sixth of the whole) leads via cell differentiation

MOLECULAR ELECTRONIC STRUCTURES
An Introduction*

Carl J. Ballhausen
University of Copenhagen

Harry B. Gray
California Institute of Technology

An introductory account of the electronic structures of atoms and molecules with emphasis on the nature of the chemical bonding in various types of molecules. After completing this text the physical chemistry student will be able to handle polyatomic inorganic and organic molecules as well as the usual diatomics and triatomics. The book is useful also for advanced inorganic chemistry courses and as a self-study unit for the chemist who needs to keep current with this rapidly moving area of modern chemistry.

Contents:

THE SCHRÖDINGER EQUATION
Formalism, The Particle in a Box, Atomic Orbitals, The Electron Spin

MOLECULAR ORBITALS
Diatomic Molecules, Symmetry Operators

MANY-ELECTRON SYSTEMS
The Pauli Principle, Atomic Electronic Configurations, and Energies

ELECTRONIC STATES OF MOLECULES
Hybrid Orbitals, Homonuclear and Heteronuclear, Diatomic Molecules, Water, Carbon Dioxide, Formaldehyde, Ethylene, Allene, Diborane, Octahedral Complexes, Potential Surfaces, Electric Dipoles

INDEX

November 1980, 144 pp., illus., 5½" × 8¼"
Hardbound 30452 $14.50

to chapters on muscle and nerve cells.

Integration of cellular and molecular matters could be improved in places; for example, discussion of self-assembly is divorced from some of its best examples, the G/F transitions of filaments and tubules, and there seems to be no hint of the possible role of glycosylation in intracellular traffic. There is a moderate if uneven emphasis on experimental evidence. For example, we meet puromycin in relation to protein synthesis, but not EGTA in excitation-contraction coupling. Though X-ray diffraction appears amongst instrumental methods, the task of explaining the importance of low-angle diffraction by intact muscle is avoided. Further there seem to be rather too many small oddities, even for a volume with so wide a sweep: EDTA works in one experiment by "binding to phosphate groups"; freeze fracture may "disclose the outer or inner surface of a membrane or may even split the membrane lengthwise". Worst, in context of cancer "normal cultured cells generally divide every 24 hours as long as they float freely in the medium". This last points to a wider weakness: of the two main tools of cell biology today, the electron microscope and cell-culture, the authors are clearly more at home with the former. Otherwise they would not propagate the myth of contact inhibition of mitosis, subsume the locomotion of tissue cells with that of amoebae, or omit all but the vaguest reference to fibronectin. The indexing could usefully be three times denser.

Nevertheless, though this book looks more successfully down the hierarchy than up, it does show that teaching centred on the cell (rather than the animal or enzyme) need not lack coherence or excitement. For such a course it would be useful but far from definitive. □

John Edwards is Senior Lecturer in the Department of Cell Biology at the University of Glasgow.

Textbook evolution

K. Murray

DNA Replication. By Arthur Kornberg. Pp.724. (W.H. Freeman: 1980.) £19.20, $34.95.

If one regards *DNA Replication* as a second edition of *DNA Synthesis,* one should read the two side by side. One then sees a remarkably concise summary of the advances in nucleic acid enzymology that have occurred in the five years that separate the two volumes, and a lucid integration of the role and interrelations of several newly discovered enzymes in the complex and intricate processes whereby genetic information is maintained and utilized. The evolution of *DNA Replication* from *DNA Synthesis* has involved a number of deletions, an appreciable amount of rearrangement and, not surprisingly since it is nearly twice the size of its progenitor, numerous insertions that confer a clear advantage upon the descendant.

The introductory chapters on the structure and functions of DNA and the biosynthesis of DNA precursors are expanded appreciably, while the chapters on DNA polymerase I of *E. coli* and other prokaryotic DNA polymerases remain largely as the classic accounts that they were, which I believe should still be read by all students of nucleic acid biochemistry — incidentally I am glad that one of my favourite quotations of Kornberg remains: "Failure to detect an enzyme activity in a cell-free extract means only that." (p.160).

It is in the discussion of eukaryotic DNA polymerases in Chapter 6 that the expansion and reorganization of material becomes really apparent. The many enzymes involved in various phases of DNA replication are now allotted individual chapters and this, in my opinion, improves the subsequent discussion of replication mechanisms and their regulation. The chapter on bacterial DNA viruses is appropriately updated and expanded, and animal viruses are similarly treated in a new chapter of their own. As before, chapters on DNA repair, recombination and restriction (and now transformation also) and on the synthesis of genes and chromosomes conclude the book. The final chapter is completely revised and introduces modern advances in DNA sequence determination and recombination DNA technology, topics that merit a book of their own. It is, as one expected, an excellent book written with clarity and an economy for transferring information which makes small bacterial viruses look extravagant, and with the authority of one who has done much to lay the foundations of the subject and set standards for others to emulate.

Like *DNA Synthesis, DNA Replication* will be widely valued both as text and as a reference book. It should be on the shopping list of all students in biological subjects — and chemists too, for that matter, in this era of biotechnology — but it will be equally valuable to research workers. If it stimulates the need for a third version, I am sure Kornberg will feel suitably rewarded. □

K. Murray is at the European Molecular Biology Laboratory, Heidelberg.

Biomembranes — agreement and discord

Dennis Chapman

Biological Membranes: Their Structure and Function. 2nd Edn. By R. Harrison and G. G. Lunt. Pp.288. (Blackie/Halsted: 1980.) Hbk £17.95; pbk £7.95, $21.95.
Introduction to Biological Membranes. By M. K. Jain and R. C. Wagner. Pp.382. (Wiley-Interscience: 1980.) £18.40, $43.25.

The ways in which a scientific consensus is reached on a subject must always be fascinating to philosophers of science. The consensus view on biomembrane structure is often expressed in terms of the fluid-mosaic model. At the same time it is appreciated by all the workers in the field that biomembranes exist which are not fluid but rigid, where the proteins are fixed in position, not mobile, and where a mosaic structure does not occur — instead, the proteins are arranged in a crystalline manner.

These topics and the relationship between structure and function are discussed in these two books. Both are up to date and deal with broadly the same area, covering electron microscopy, membrane preparations, structural organization, transport and receptor functions. The book by Jain and Wagner is perhaps the more elegantly written, and contains good diagrams with clear summaries and useful references, but both books will be useful to graduate and undergraduate students interested in having a concise review of the present situation.

Given two such similar books, it was interesting to see how they discussed an area of research which has excited interest over the last two or three years. This is the topic of protein–lipid interactions in biomembranes. Jain and Wagner comment

> . . . various lipid activated enzymes contain an annulus of tightly bound lipid molecules . . . . Such lipid has distinctive properties, cannot be readily extracted, is *not* readily exchangeable with the more fluid lipid . . . .

Harrison and Lunt comment

> . . . a number of membrane-bound enzymes have been shown to be surrounded by an annulus of immobilized boundary lipid, the local phase transitions of which are reflected in the activity of the enzyme . . . and boundary lipid does not preclude *rapid exchange* with surrounding lipid molecules.

Perhaps in the next editions a new consensus view on boundary lipids will be reached! However these quotations merely show how difficult it is to give a snapshot impression of a scientific area which is still alive and active. □

Dennis Chapman is Professor of Biophysical Chemistry at the Royal Free Hospital School of Medicine, University of London.

Introductory chemistry in the market place

Arden P. Zipp

Fundamentals of Chemistry. 4th Edn. By F. Brescia, J. Arents, H. Meislich and A. Turk. Pp.781. (Academic: 1980.) $21.95, £13. *Foundations of College Chemistry.* 3rd Edn. By D. B. Murphy and V. Rousseau. Pp. 767. (Wiley: 1980.) $29.20, £12.45. *Basic Chemistry: General, Organic, Biological.* By D.M. Callewaert and J. Genyea. Pp.837 (Worth: 1980.) $19.95, £9.25.

THE teaching of introductory chemistry has given rise to much discussion in recent years due to two main factors. The first of these concerns the question of the topics to be taught and the level of presentation to be attempted. The second has to do with the wide variation in the abilities of the students who take such courses. These range from individuals who have received good preparation in secondary school and have little difficulty dealing with the abstract concepts which are inherent in the subject matter, to students who are ill-prepared to deal with these concepts. Although the second factor may be more common to US colleges and universities, it would be surprising if it were totally absent from classes in other countries as well.

In order to compete in the current market, textbook authors are called upon to provide books which are both broad in scope and flexible in level. The three discussed here are intended to accommodate students of varying backgrounds with potentially different career goals who need a general chemistry course; that is, students who are likely to major in science although not necessarily in chemistry. Despite this common objective, and a number of similarities among them, these books actually provide a wide choice in level and approach, and each offers something unique.

Each book is about 800 pages in length, has been produced in an attractive manner with an extensive use of colour, and all seem to have been well-edited with few errors. All three cover the topics usually treated in general chemistry: stoichiometry, atomic structure, bonding, states of matter, thermodynamics, equilibrium, kinetics, acids and bases, electrochemistry, elementary organic chemistry, polymers and (except for Callewaert and Genyea) coordination and nuclear chemistry.

Of the three, the book by Brescia *et al.* seems to be the most student-orientated, each chapter containing learning objectives, key terms, self-tests, worked-out examples and many practice problems, with answers given in an appendix. (A companion student guide is also available for this text.) Each of the other books possesses only some of these features. The authors have adopted the technique of presenting topics more than once, first on a qualitative level, then on a more intensive basis. Although this approach is successful in most cases, it is surprising to find the second stage of bonding deferred to Chapter 20 after the initial treatment has been presented in Chapter 9. The bulk of thermodynamics is presented as it relates to phase changes, rather than in a more abstract fashion. Descriptive chemistry appears mostly as a means of illustrating principles rather than in a separate chapter or chapters. A chapter dealing with environmental chemistry is presented, as is one on radiation and matter. The latter provides coverage of infrared, ultraviolet, nuclear magnetic resonance and mass spectroscopy in much greater depth than is usually encountered at this level, although some instructors may find it appropriate.

The text by Murphy and Rousseau is the highest in level mathematically and provides the greatest emphasis on physical chemistry. It presents numerous derivations including the Bohr radius, van't Hoff and Balmer equations, and the gas laws (from kinetic theory). Three centre bonds (boron hydrides) are discussed in some detail and the Debye–Huckel theory is mentioned. It is the only one of the three books in which descriptive chemistry is discussed separately. A 35-page chapter on group IV (emphasizing the variations in properties observed as the family is descended) precedes a chapter on organic chemistry, which is followed in turn by one of 57 pages in which the remaining non-metals are discussed. A separate chapter on metallurgy is also presented. The book offers many problems, both worked-out in the text and at the ends of chapters (with answers to odd-numbered ones given in an appendix), and provides a list of suggestions for further reading after each chapter. In addition, a student guide and solutions manual are available.

The distinguishing feature of the Callewaert and Genyea text is the heavy emphasis on organic and biological chemistry. Approximately one-half of the book is devoted to "general" chemistry with the remainder being divided about evenly into three sections devoted to organic molecules, biological molecules and metabolism. In addition, many of the examples used in the first portion of the text are biochemical in nature. This text was the hardest one for me to evaluate, having had little experience teaching such a course. Although the authors say that their intent is "explaining essential chemical concepts rather than providing a cursory treatment of a much larger number of topics", some of the discussions seem too brief to provide a real understanding of the material. For example, kinetic molecular theory, solids, liquids, gases and elementary thermodynamics are discussed in a chapter of 27 pages. Similarly, equilibrium and kinetics (including the disproven direct collision mechanism for the H_2–I_2 reaction) are "covered" in 21 pages. Further, it is surprising to find electron configurations relegated to an optional section of a chapter and to encounter a discussion of bonding without substantial use of orbitals. This approach may be appropriate and even necessary in order to cover all the material included in the text (and presumably in such courses), although the book's use in the broad general chemistry market is likely to be limited. The book does give study objectives, useful chapter summaries and solutions to exercises at the end of each chapter, but has relatively few problems and worked-out examples and is the least mathematical of the three.

These three texts represent only a small sample of the total number which is currently available, although they do provide some indication of the almost limitless variety which exists in this highly competitive market. ☐

Arden P. Zipp is Professor of Chemistry at the State University of New York, Cortland, New York.

Biophysical challenge

R. G. Gosling

Topics in Classical Biophysics. By H. J. Metcalf. Pp.286. (Prentice-Hall: 1980.) Pbk £6.45, $9.95.

MY readiness to review this book lay in its intriguing title and my need of a broadly based text for students pursuing a BSc degree in "physics with medical applications". The format is primarily that of a textbook, although the author suggests it "is not intended for students alone". The first eight of its nine chapters present appropriate basic theory — biomechanics, heat and energy, fluids, blood circulation, feedback and control, nerve cells, sound and hearing, light, colour and vision. The final chapter is a somewhat mixed bag entitled "Experimental Techniques" but, with its emphasis firmly on the use of physics to acquire information, nicely draws together the joint application of various principles previously discussed.

Essentially, the theoretical treatment is that of classical continuum physics, with basic equations developed at the beginning of each chapter and then applied to some selected topics appropriate to that field. Whilst the question as to whether this justifies the title *Classical Biophysics* could be debated, I found that the material chosen represented a useful introduction for any undergraduate interested in the applications of physics to medicine. The only pre-requirement is an elementary knowledge of calculus, for example additional maths at "O" level in the UK or an introductory year college math course in the USA.

Because of the wide range of natural phenomena discussed, the theory that can be developed in the commendably brief compass of 275 pages is necessarily kept at a lowish level. The penalty is that arguments are sometimes terminated a little prematurely. For example, in Chapter 3 on fluids, the forces acting in a Newtonian liquid flowing in a rigid tube are clearly deduced, but then used only in the special case of a constant pressure gradient. This precludes any application of such theory in discussing arterial haemodynamics in the next chapter. However, it does provide a clear "launching point" for any lecturer using the book as a class text.

It is my impression that this book will present first- and second-year students of physics, biology or medicine with challenging reading and I look forward to using it with such classes next year. It may prove a useful introduction to any courses concerned with the application of classical physics to biomedical problems. ☐

R. G. Gosling is University Reader in Physics Applied to Medicine at Guy's Hospital Medical School, University of London.

Food — science and politics

J.W.T. Dickerson

Nutrition: in Perspective. By Patricia A. Kreutler. Pp.700. (Prentice-Hall: 1980.) £12.30, $18.95. Workbook also available.

THERE has recently been something of a spate of books on nutrition, and new ones must therefore face increased competition. The market itself has also increased, for we are becoming much more aware of the relevance of food to life and health in the modern world. Moreover, all shades of interest and competence, from the lay reader to the academic, can profit from the study of the subject. This book has been aimed somewhere in the middle of the range. It "has been written to provide students with an understanding of the science of nutrition"; to acquaint them "with the issues facing nutritionists, scientific and government leaders, and consumers in contemporary society", and "to enable students to translate knowledge into practice".

The first part of the book is concerned with the scientific principles of nutrition, and contains nine chapters. The second part discusses aspects of nutrition for everyday living, in seven chapters. The author and publishers are to be congratulated on the plan and layout of the book. The text is clear, direct and liberally illustrated throughout with tables, figures, photographs and the occasional cartoon. The author is clearly an expert communicator of her subject. References in the text have been kept to a minimum and are listed, with recommendations for additional reading, at the end of each chapter.

A feature of the book is the introduction, as appropriate, of "Perspectives" — applications to health or topics of contemporary concern. Thus, in the chapter on carbohydrates, the perspectives are sugars in foods, diabetes and hypoglycaemia, and dietary fibre. The chapter on lipids contains a perspective on diet and heart disease. Perspectives on sodium and hypertension, iron enrichment and the politics of fluoridation are inserted in the chapter on minerals, whereas fad diets are discussed in the chapter on food in contemporary society.

The whole book is a pleasure to read. It is interesting, informative and contains a great deal of valuable information. ☐

J.W.T. Dickerson is Professor of Human Nutrition at the University of Surrey.

Chemistry for life

Peter Garratt

Essential Organic Chemistry for Students of the Life Sciences. By A.P. Ryles, K. Smith and R.S. Ward. Pp.306. (Wiley: 1980.) Hbk £14.90, $44.10; pbk £5.25, $15.75. *Organic Chemistry: The Basis of Life.* By Bernard Miller. Pp.472. (Benjamin/Cummings/Addison-Wesley: 1980.) $18.95, £11.85.

THE problem of teaching chemistry to students in the biological sciences is one of striking a balance between relevance and comprehension. The student, who probably has no great interest or aptitude for chemistry, wants only that material which is immediately relevant to his biological studies, whereas the teacher knows that to have any appreciation of the role of chemistry in biology the student must understand the concepts and principles on which the subject is based. These two books, although emanating from different continents and very different educational systems, clearly illustrate that this problem is also felt by writers of texts for such students.

Both books deal, as their titles imply, only with the organic component of the chemistry required by biologists. RSW (for short) has three introductory chapters, the first on bonding, functional groups and mechanism, the second on stereochemistry and the third on techniques. Then follow nine chapters presenting a conventional and systematic treatment of organic chemistry from the alkanes to the proteins and nucleic acids. The last three chapters deal with tetrapyrroles, physiologically important compounds and metabolism and biosynthesis. Miller has an introductory chapter in which "basic principles" are sketchily and sometimes erroneously treated, followed by a chapter on the alkanes whch includes further introductory material on bonding. The remaining 16 chapters give a similar outline of organic chemistry to that found in RSW, except that the ordering of material differs. For example, chirality is introduced on p.23 in RSW but not until p.197 in Miller, rather late for a book subtitled the *Basis of Life.* Miller integrates the biological examples more intimately with the chemistry than do the British authors, and each chapter ends with a summary of the important principles and concepts found therein. Both texts have problems distributed within the chapters, and there is a student study guide available for Miller and one promised for RSW.

The layout, appearance and style of a text are important to its student user. Both texts are well produced, Miller being a two-colour printing, in which the colour has been judiciously used, while RSW is in monochrome. Miller has clear structural diagrams and well drawn, and therefore useful, representations of space-filling models, but it also has unnecessary photographs of oil rigs and similar irrelevant objects. RSW has, in general, clear structural formulae except for those representing the conformations of cyclohexane and for ascorbic acid, the nicotinamide co-enzymes and co-enzyme A. RSW also uses Haworth rather than conformational formulae for the carbohydrates. Since shape is so important for biological activity, conformational structures are much more instructive, and the treatment in Miller, which uses such structures, is clearly superior.

Both of these texts would form a satisfactory basis for a course in organic chemistry for biologists, but whether much would be gained over using a standard chemistry text such as Solomons' *Organic Chemistry* (Wiley, 2nd Edn 1980 — see over for review) is a moot point. Miller certainly makes a more direct attempt to show the relevance of the chemistry to biological molecules and processes than does RSW and the style is easier to read, but the sections on orbitals and bonding would require remedial attention from the lecturer. ☐

Peter Garratt, a Reader in the Department of Chemistry at University College, University of London, regularly lectures to biology students on chemistry.

Organic chemistry, in theory . . .

John Mann

Organic Chemistry. 2nd Edn. By T. W. G. Solomons. Pp.1066. (Wiley: 1980.) Hbk £15.25, $33.25; pbk £7.90, $18. *Organic Chemistry.* By D. S. Kemp and F. Vellaccio. Pp.1421. (Worth: 1980.) Hbk $26.95, £10.25; pbk $14.95, £5.

It is not often that an organic chemistry textbook is the subject of a plagiarism suit, but such was the fate that befell the first edition of *Organic Chemistry* by T. W. G. Solomons. After a four-month hearing the book and its author were cleared in March 1980, just prior to the release of the second edition. Personally, I have always found the other book in question (*Organic Chemistry* by R. T. Morrison and R. N. Boyd; Allyn & Bacon, 3rd Edn 1973) pretty indigestible and rather old-fashioned, though students seem to like the summaries of functional group chemistry.

Professor Solomons's book has similar summaries at the end of most chapters, but it also has a great many features which enhance its value relative to Morrison and Boyd. The order of treatment is conventional, commencing with hydrocarbons and bonding, and proceeding through the various functional groups to carbohydrates and proteins. Well-chosen special topics are interspersed throughout, and complement the chapters in which they appear. We thus have naturally-occurring alkenes and the photochemistry of vision at the end of the chapter on conjugated unsaturated systems; a beautifully illustrated and lucid account of protein biosynthesis accompanies the chapter on amino acids and proteins; and there are also useful sections on applications of the Woodward–Hoffmann rules, halo-organic insecticides, polymerization, and biosynthesis of fatty acids and steroids. One small puzzle is why thallation deserves a six-page section of its own, while the Wittig reaction and organosulphur chemistry (both much more important in modern organic chemistry) receive only scant attention. The chapter on spectroscopic techniques, now a must for any organic text, provides a very good introduction to the subject, and is comparable with the corresponding section in *Introduction to Organic Chemistry* by A. Streitweiser and C. H. Heathcock (Macmillan, New York, 1976), the book that we recommend to our students.

There are a few disappointments in Professor Solomons's book. For example the absence of a section on the strategy of synthesis, and the rather old-fashioned account of synthesis and reactions of β-dicarbonyl compounds which contains a long list of named reactions, but little in the way of modern synthetic applications or mention of their relevance to biochemistry. These criticisms aside, the main functional group chemistry is well done, the book is beautifully produced with two-tone drawings and section headings, and there are clear chemical structures throughout. It is readable and reasonably up-to-date in most areas, and has innumerable useful problems throughout, with answers supplied at the end of the book or in the separate solutions manual.

The authors of the second glossy American book under review, D. S. Kemp and F. Vellaccio, claim that there is a need for a text emphasizing the chemistry of the oxygen- and nitrogen-containing functional groups. The book is designed for an American one-year/three-semester course (as I suspect Solomons's book is), and it is divided into three main parts: chemistry of functional groups and structure proof; chemistry of hydrocarbons and carbonyl chemistry; and advanced topics. The order of treatment is thus somewhat different from that of most other texts. Apart from this difference, the treatment of topics is rather similar to that in Solomons, except that there is more emphasis of applications to organic synthesis. The authors claim that their treatment of carbonyl chemistry is the "most accessible and interesting of any that are available", and in this they are probably correct. The chapter on spectroscopic methods provides a good introduction to NMR and IR, but is very weak on mass spectrometry (a mere three and a half pages), while chapters on carbohydrates, proteins and nucleic acids are good, though not so well done as in Solomons. There are good sections on the Woodward–Hoffmann rules; rearrangement reactions; reactive intermediates; and organometallic reagents, which includes as special topics hydroboration, silanes, organomercury compounds and thallation. Coverage of heterocyclic chemistry is, however, rather weak, and natural products are dealt with in a somewhat fragmented way. The penultimate chapter, on the synthesis of six compounds of theoretical or practical importance, is novel and makes interesting reading. It includes, amongst other topics the conversion of penicillins into cephalosporins, and capped porphyrins. Again, there are useful problems throughout, and the 670-page workbook and solutions manual should find many friends amongst both students and academics. Throughout, the illustrations are very good, but the book is not quite so lucid or readable as Solomons, and many students will miss the reaction summaries.

Both books are modern texts comparable to the excellent Streitweiser and Heathcock, and will I am sure sell well, especially in the USA. However neither of them has everything quite right, and the ultimate text has still to be written. But then, there is probably no such thing! □

John Mann is a Lecturer in Organic Chemistry at the University of Reading.

. . . and in practice

Paul Schatz

Experimental Organic Chemistry. By Michael P. Doyle and William S. Mungall. Pp.490. (Wiley: 1980.) Hbk £10.10, $23.70; pbk £5.95, $13. *The Systematic Identification of Organic Compounds.* 6th Edn. By R.L. Shriner *et al.* Pp.604. (Wiley: 1980.) Hbk £13, $30.55; pbk £6.90, $15.90.

The pedagogical aim of an organic laboratory course is to introduce the student to the basic techniques used by chemists for the preparation, separation, purification and identification of organic compounds. Besides demonstrating such techniques as distillation, recrystallization, chromatography and extraction, the laboratory is a showplace for demonstrating the chemical properties of the various organic functional groups. Most introductory laboratory courses use what might be dubbed "the synthetic approach". The techniques are introduced in the context of carrying out typical organic reactions, such as an Sn1 substitution or an E2 elimination, isolating and purifying the product, and confirming the identity of the product. An alternative approach to teaching in the organic chemistry laboratory could be called "the characterization approach". In this approach, the laboratory techniques are taught in the context of classifying and identifying organic compounds by functional groups. Typically, derivatives of compounds are prepared and purified, and then identified by measuring physical properties. Although most qualitative analysis courses are usually reserved for intermediate or advanced level undergraduate students, many modern introductory courses employing the "synthetic approach" also incorporate a qualitative analysis component into the curriculum.

There are a large number of textbooks (or laboratory manuals) available for the introductory laboratory and the manner in which they treat the material is very similar. There is a section introducing basic techniques, there is a section on qualitative analysis and there is a section containing a variety of experiments for the instructor (or student) to choose from. *Experimental Organic Chemistry* follows a similar pattern. What distinguishes it from other texts are the experiments. They are not a rehash of familiar experiments, but a set of new ones. Moreover, they are interrelated since the product of one experiment can serve as the starting material for another. The authors suggest that besides being educationally beneficial, it can also whittle down the cost of the laboratory course. By choosing readily available chemicals for both the starting materials and the products, the authors have avoided the pitfall of locking the user into a prescribed set of experiments and the vexing problem of what to do with the student who gets a poor yield. The variety of experiments is impressive — Sn1 substitution, Sn2 substitution, enzymatic hydrolysis, phase transfer catalysis and so on — and they include a good collection of short multistep (two or three steps) syntheses. The book has much to recommend it besides the experiments. The techniques are explained fully and clearly, the experimental procedures are detailed and clear, the artwork is accurate and well drawn, and the reproductions of the IR and NMR spectra are sharp. All in all, this is a well crafted book, definitely one to be considered when choosing a text for laboratory courses.

One of the most familiar books for the organic qualitative analysis course has been *The Systematic Identification of Organic Compounds.* A sixth edition has been recently published and this edition is markedly different from its predecessors. The most obvious difference is the size; the newest edition is approximately 50% wider than the fifth edition. This larger size is needed to contain the expanded text. For the most part, all of the elements of the older editions are incorporated in this edition, including the measurement of physical properties, the classification tests, the preparation of derivatives and the comprehensive tables of derivatives. What has been added are more extensive discussions of spectroscopic methods of identification and chromatographic methods of separation. The latter topic was completely omitted in previous editions.

Other additions are a larger introduction, including a discussion of laboratory safety, a more detailed explanation of basic laboratory techniques such as distillation and recrystallization, and a chapter on the literature of organic chemistry (principally an annotated bibliography). The book would be useful for the classic organic qualitative analysis course (if any of these still exist). It could also be used in an introductory organic laboratory course emphasizing qualitative analysis if supplementary material describing the theory of the basic techniques is available, since no theory is explained in the text. □

Paul Schatz is Director of Organic Laboratories at the University of Wisconsin-Madison.

Joys of general chemistry

Charles A. McAuliffe

Chemistry (With Inorganic Qualitative Analysis). By T. Moeller *et al.* Pp.1085. (Academic: 1980.) £14, $21.95. *Chemistry: A Systematic Approach.* By Harry H. Sisler, Richard D. Dresdner and William T. Mooney Jr. Pp.960. (Oxford University Press: 1980.) £13.50, $19.95. *First Year Chemistry.* By J. M. Coxon, J. E. Fergusson and L. F. Phillips. Pp.376. (Edward Arnold: 1980.) Pbk £9.75.

I HAVE been reviewing freshman chemistry texts for this edition of *Nature* for four years and, despite a long association with a number of American universities and their methods of teaching, each particular year of carrying out this task offers me an opportunity of seeing new facets in these books. For example, the best of this type of book, in addition to expounding chemical fact and theory, also stresses the application of chemistry to everyday life. I have been particularly pleased by attempts in a number of excellent texts at the way in which environmental problems are related to the chemistry being illustrated. For example, consideration of the reactions involved in the generation of photochemical smog cannot only make a student appreciate the chemistry of the nitrogen oxides and ozone, but also that of organic free radicals and the importance of light in initiating chemical reactions. Similarly, dealing with elemental cycles in the biosphere not only emphasizes their importance to life but also serves to make simple chemistry very real; for example, the most important of all chemical processes, photosynthesis, should not be dealt with in isolation, large subject though it is, but can in a freshman text be linked to the oxygen and carbon cycles and fossil fuel generation.

The enormous market for freshman (or general chemistry) texts in the United States ensures that many are available. In previous years I have emphasized how awful some of these texts are, and one shudders to think of them being foisted on students by their authors; many potentially creative chemists must be lost in this way. However, the three texts dealt with here are, in their different ways, a joy to behold.

Chemistry (with Inorganic Qualitative Analysis) has so much to recommend it. There are 32 chapters and it is sensible to give a brief indication of their range so that one can understand the scope of a large textbook such as this. Atomic structure and nuclear chemistry, chemical bonding, periodic properties, thermodynamics, kinetics and electrochemistry provide an adequate theoretical basis. Descriptive group chemistry and some, though never enough, organic chemistry is related to reactivity and stoichiometry. There are several chapters on qualitative analysis.

It is difficult to single out individual sections of this book for praise. I used the extensive index a great deal in examining the book. Nothing which should be included has been omitted; the text is concise and illuminating. Like many such books, the diagrams are excellent. I particularly enjoyed the copious vignettes entitled "Thoughts on Chemistry". These are enlightening quotes, a page or so in length, which range from "The Requisites of a Good Hypothesis" (Robert Boyle), "The World's Biggest Membrane" (from Lewis Thomas's memorable observations in *The Lives of a Cell: Notes of a Biology Watcher*), "The Chemical History of a Candle" (Michael Faraday), "The Centrality of Chemistry" (Martin Sherwood), to "The Epigrams of Remigius Fresenious". This book is to be highly recommended. I have only two criticisms. The minor criticism is that on the same page (p. 21) which shows the structure of chlorophyll *a* there is advice on how to pronounce $NaNO_3$ ("N-A-N-oh-three") and H_2SO_4 ("H-two-S-oh-four") — this grated on me. More serious is the large amount of space they devote to inorganic qualitative analysis. This is a grindingly boring topic and, if included at all, should be kept to a minimum. The authors would do well to extend their good descriptions of infrared, ultraviolet and nuclear magnetic resonance spectroscopy.

Chemistry: A Systematic Approach is also to be recommended. It is comprehensive and I particularly enjoyed the chapter on the chemistry of living systems. An instructor's manual (by W. H. Myers) is available.

First Year Chemistry is a somewhat different book. The authors aim to produce a text in which approximately equal weight is given to physical, inorganic and organic chemistry, and minimizes the divisions. It is a very good attempt, but the book may have limited appeal. It assumes a much greater basic knowledge than do the other texts and may be only suitable for the New Zealand system, in which the authors work.

Finally, might I appeal to all of these authors? Expressing photosynthesis as

$$6CO_2 + 6H_2O \rightarrow C_6H_{12}O_6 + 6O_2 + \text{energy}$$

is very misleading, even though this is the way major biology texts frequently express it. Carbon dioxide does not react with water as implied by the equation. Further explanation would be enlightening □

Charles A. McAuliffe is Reader in Chemistry at UMIST and Adjunct Professor of Chemistry at Auburn University, Alabama.

Quantum mechanics for chemists

A. J. Stone

Orbitals and Symmetry. By D. S. Urch. Pp.256. (Macmillan: London, 1979.) Pbk £5.95. *Chemical Structure and Bonding.* By R. L. DeKock and H. B. Gray. Pp.491. (Benjamin/Cummings/Addison-Wesley: 1980.) $21.95, £9.95.

THE flood of textbooks on quantum mechanics for chemists puts one in mind of that wilderness of monkeys which are supposed in time to produce the works of Shakespeare — not because the results are similar but because we are prompted to ask: why bother? We already have textbooks at every level which give clear, sound coverage of the principles of the subject. It is not enough for a new book to do the same; it must provide new insights, take account of advances in experimental and theoretical technique, or treat some aspect of the subject substantially better than before.

DeKock and Gray's angle is to relate the discussion of bonding and structure to the results of photoelectron spectroscopy. However, the book begins with the Bohr theory (what other superannuated theory has such resilience that it is still being taught 50 years after it was superseded?) and there is much emphasis on Lewis octets and valence-shell–electron-pair repulsions. Valence-bond theory is discussed at length, and molecular-orbital theory takes a bad second place. For example, a superficial and rather inaccurate account of a simple Walsh diagram is followed by the statement that "predicting molecular shape using molecular-orbital theory. . . is much more tedious than the valence-shell electron-pair repulsion method". This attitude to molecular orbital theory is curious in view of the detailed account of the relationship between photoelectron spectroscopy and bonding, which is the one useful feature of the book and which is done rather well — indeed, at a level which is noticeably higher than the rest of the book.

Urch's book is a reprint of a volume originally published in 1970 in the abortive Penguin Library of Physical Sciences, and although the preface implies some revision of the text, this version looks virtually identical to the original. Some errors have been corrected, but others have not, and the bibliography remains unchanged. My main criticism is that there is not enough attention given to the business of showing the student how to do the calculations. For example, the representation matrices for a set of d orbitals in the octahedral group (a notorious source of difficulty) are simply written down without comment. More importantly, the procedure for obtaining symmetry orbitals (the projection formula) is never mentioned, and symmetry orbitals are blandly produced, not merely without explanation but without any apparent appreciation that the reader might not see where they came from. The text could quite easily have been revised to correct these failings, but the opportunity has been lost and a potentially useful account remains incomplete.

A. J. Stone is a Lecturer in Theoretical Chemistry at the University of Cambridge.

Environmental chemistry, theory and practice

Roy M. Harrison

Environmental Chemistry: The Earth–Air–Water Factory. By R. W. Raiswell *et al.* Pp.184. (Edward Arnold/Halsted: 1980.) Flexi £4.95, $14.95. *Experiments in Environmental Chemistry: A Laboratory Manual.* By P. D. Vowles and D. W. Connell. Pp.102. (Pergamon: 1980.) Hbk £10, $23; pbk £4.50, $9.95.

THE teaching of environmental chemistry as a component of environmental science, ecology and chemistry courses at university level has developed and expanded considerably over recent years, largely in the absence of adequate textbooks. A number of books have appeared recently, but there still exists a need for sound teaching texts.

Environmental Chemistry: The Earth–Air–Water Factory provides a broad introduction to the field written mainly from the viewpoint of the geochemist. The factory analogy is used apparently in an attempt to provide a better integration of subject matter and to encourage the student's appreciation of the strong links between the various areas of environmental chemistry. The book assumes rather little chemical background and even includes a glossary of chemical terms. It is written with clarity by authors acknowledged as authorities in their respective fields. The great detraction, however, is that no text of 154 pages (excluding glossary and index) can more than touch the surface of this vast subject area. It is difficult to see the book being used for university teaching other than at the most basic level as it will satisfy neither the lecturer's aims nor the student's curiosity.

Experiments in Environmental Chemistry: A Laboratory Manual concentrates upon pollution and ecological chemistry, the majority of experiments being analytical in nature. The presentation is similar to that used in laboratory manuals in universities, with an introductory section followed by experimental instructions and then guidance for writing up. The factual material is occasionally unreliable, although in some instances this arises from typographical errors. The experiments require a fair variety of analytical equipment which may be beyond the resources of some teaching laboratories, and some demand rather problematic starting materials — human milk; butterfly larvae and plants from the Southern Hemisphere; replicate 0.2 g samples of household paint removed from surfaces, for example. The book contains some excellent ideas for experiments but is more likely to find use as inspiration for the teacher than as a laboratory manual used directly by the student. □

Roy M. Harrison is a Lecturer in the Department of Environmental Sciences at the University of Lancaster.

Environmental what?

John Barkham

Ecology and Environmental Management. By C. C. Park. Pp. 272. (Butterworths/Westview, Boulder, Colorado: 1980.) £12.50, $26.25. *Natural Resource Conservation: An Ecological Approach.* 3rd Edn. By Oliver S. Owen. Pp.883. (Macmillan, New York/Collier Macmillan, London: 1980.) £12.95, $19.95. *Introduction to Environmental Science.* By J.M. Moran, M.D. Morgan and J.H. Wiersma. Pp.658. (W.H. Freeman: 1980.) £19.95, £9.80. Instructor's guide also available.

MANY different disciplines contribute to attempts to understand the environment. The rapid development of courses in environmental sciences or studies in recent years reflects the need to look beyond geography, geology, biology or economics alone for the range of material required. However, the variety of university and college courses calling themselves "environmental" suggests widely differing views as to what are the key subject areas, concepts and techniques to which students should be addressing themselves. That there are degree courses in "environmental *science*" implies that there are those bold or unwise enough to define a distinct discipline. A more sensible and pragmatic approach is to regard the sciences concerned with the environment as a federation. They may usefully be gathered together in one department so that environmental problems may be explored from a number of different perspectives. This flexible view allows students to adopt an eclectic approach to learning, drawing upon sources of information which appear to be useful whatever their pedigree may be. So it is likely that books written about environmental sciences from a variety of points of view will be useful to different students at different times.

The three books considered here all examine problems of environmental management from an ecological perspective. They appear to be directed towards first-level university and college courses. Questions of management always stimulate student interest and passion, but the soundness with which undergraduates approach such issues usually depends upon the adequacy of their grounding in basic biological, environmental and social sciences. All three books start from the assumption that their readers know little or no ecology and attempt to give them a grounding in it. Park's book, *Ecology and Environmental Management*, devotes about 170 pages to this material, about two-thirds of the book, although the first 20 pages are spent in largely sterile justification of the notion that geography is "centrally placed to contribute effectively to the solution of many environmental problems". This section rather underlines the fact that this is an ecological text written by a geographer for geographers and environmental scientists. Ecologists will find the balance rather odd and it is by no means clear at times why, in relation to environmental management, we should be learning the details of some ecological processes. There are some extraordinary statements, too, including a comment on the ". . . lack of interest within ecology for animal populations . . ." (p.39). For me, there is a definitely dated feel to the first two-thirds of this book, which is perhaps emphasized by the predominance of geographical references and the paucity of ecological ones from the 1970s.

In Owen's book, *Natural Resource Conservation*, the ecological basis provided is the barest minimum necessary and is rather scattered about within the text following a short section near the beginning. Moran, Morgan and Wiersma's *Introduction to Environmental Science* is the best balanced from this point of view, although the title is entirely misleading. Ecological fundamentals occupy about as much space as in Park's work, the approach is traditional — but none the worse for that — and, above all, the material is well organized. It is obviously a carefully planned book and I wonder whether this is the pay-off for good teamwork. There are conclusions, useful summary statements, review questions and boxes of information where deeper explanation of a topic is felt necessary.

In the environmental management sections, Owen's and Moran *et al.'s* American texts are very different from Park's English approach. Having waded through Owen I felt blasted with the sheer volume of material on every kind of resource and pollution problem. No question of a balanced view here. I felt the author wanted the reader to join him in the corral of the good boys. However, there is a lot of qualitative information about every kind of problem, solutions are discussed and the work is liberally illustrated. Moran *et al.* cover the same ground in about the same amount of space but in a well-ordered, less frenetic manner and with fewer gee-whiz statistics. Both books use very largely American case studies and examples and refer to American ways and means of tackling these problems.

Park's book examines resource, pollution and management issues relevant to Britain. Only two pages are devoted to problems of a global scale. Students concerned with nature conservation will find a lot of useful material, particularly in the tables. Others taking a broad-based course will get a reasonable overview of the subject.

In terms of a best buy, Owen's book may well appeal to a section of the American market, but not in Britain. Park's will have a limited appeal mainly to geographers in Britain, but not in America. Moran *et al.* is best value for money and may sell to a limited extent in Britain as well as in America, although a title such as *An Ecological Approach to Environmental Management* would be more appropriate. Sadly, none of these books succeed in giving the student a clear global perspective which is not at the same time banal. It is also clear to me that any student who is exposed only to the approach adopted here will make a disastrous environmental manager. □

John Barkham is in the School of Environmental Sciences, University of East Anglia.

Views of the landscape

C. Kidson

Process in Geomorphology. Edited by C. Embleton and J. Thornes. Pp.436. (Edward Arnold/Halsted: 1979.) Hbk £16, $44.95; pbk £8.95, $19.95. *Geomorphological Processes.* By E. Derbyshire, K. J. Gregory and J.R. Hails. Pp.312. (Butterworths/Westview, Boulder, Colorado: 1979.) Hbk £12.50, $31.25; pbk $13.50.

It is now more than 30 years since the famous symposium, commemorating the centenary of the birth of W. M. Davis, marked the beginning of the so-called "new" geomorphology of which these two texts, in their differing ways, are examples. In 1952, in "The Dynamic Basis of Geomorphology" *(Bull. geol. Soc. Am.* **63**, 923–938) Strahler amplified the "dynamic approach" advocated at the symposium, which required the quantitative determination of landform characteristics and the formulation of empirical equations by the methods of mathematical statistics. This "counterbalance" which, he felt, should replace the Davisian explanatory descriptive method, involved

> the study of gravitational and molecular shear stresses acting on the materials of the earth's surface, which behave as elastic or plastic solids, or viscous fluids to produce the characteristic varieties of strain or failure that constitute weathering, erosion, transportation or deposition.

Process in Geomorphology and *Geomorphological Processes* both adopt this approach but with differing degrees of emphasis and with differing success. The first is almost a caricature where the landform characteristics appear frequently to be forgotten and mathematical statistics and empirical equations seem, at times, to be incorporated for their own sakes rather than to make an understanding of the operation of processes easier. Indeed, some of the authors have succeeded in making relatively simple topics seem difficult. Even final-year undergraduates will have difficulty with parts of this volume, especially if they have no background in physics and hydraulics. The excellent introductory chapters go some way towards helping such students. *Geomorphological Processes* succeeds in adopting a rigorous approach but in a more balanced way, maintaining a clarity of mathematical as well as of verbal expression which illuminates rather than confuses.

In *Process in Geomorphology* two other defects mar what is, nonetheless, a useful compendium of scholarly essays. The idea that landforms may encapsulate the results of many processes, of which those now seen in operation are but the most recent, finds no place in the book. Changes of climate and of process over time, for example those resulting from the advances and retreats of Pleistocene ice sheets, are largely ignored. Second, rates of operation of processes, particularly in the context of the rare event, are inadequately considered by most of the authors. The concluding chapter by Dr Thornes does nothing to remedy these defects.

Geomorphological Processes similarly concentrates on contemporary processes and to some degree suffers from the same defects. However, the short introductory chapter makes clear that this is a conscious choice and indicates the need to examine these other facets of landform developments, at greater length, elsewhere.

Derbyshire, Gregory and Hails succeed in making their study an exercise in of the landscape, by constantly maintaining the link between process and form. This is made possible by the arrangement of the book. Essentially, processes are divided into glacial and periglacial, fluvial and marine with only a small chapter devoted to the work of the wind. A much shorter introduction than in the Embleton and Thornes volume allows each of the three major sections to be treated at greater length. The effect is most marked in Hails's chapter which is a full and authoritative treatment of coastal processes. By contrast, Clark in *Process in Geomorphology,* asked to attempt a similar geomorphology, rather than in the physics exercise in half the space, not unnaturally makes a more superficial presentation.

These two volumes are interesting for contrasts in style rather than in approach. Both have value. *Process in Geomorphology* will be useful to the readers to whom it is directed much more as a reference work than as a course primer; *Geomorphological Processes* could well satisfy the opposite function. □

C. Kidson is Professor of Physical Geography and Head of the Department of Geography at The University College of Wales, Aberystwyth.

Sedimentary, my dear Watson!

Bruce Sellwood

Origin of Sedimentary Rocks. 2nd Edn. By H. Blatt, G. Middleton and R. Murray. Pp.782. (Prentice-Hall: 1980.) £20.10, $30.95.

UNTIL the middle of this century the study of sedimentary rocks fell largely under the two headings of stratigraphy and petrology. Sedimentology as a separate integrative discipline emerged no more than 30 years ago and a major surge in the subject has occurred over the past 20 years, much of the impetus for new developments coming from the demands of the oil and mineral extraction industries.

One of the first integrative modern sedimentological texts was *Origin of Sedimentary Rocks* (Prentice-Hall, 1972) which stressed the genesis of sediments and the processes of physical and chemical sedimentation. At that time the book was generally welcomed as a well organized, comprehensive and admirably clear text. After eight years, a totally revised edition has appeared. The new edition is almost 25% longer than the original but retains the successful structure and stylistic clarity of its predecessor. The book is divided into six parts and contains 19 chapters, each of which ends with a useful annotated reference list.

Part I introduces the scope of sedimentology, emphasizing the role of field investigation. Discussion of various facets of the geological cycle is undertaken in Part II.

Part III is a review of terrigenous clastic sediments, and commences with a new and welcome chapter on the geochemistry of natural waters. This is followed by coverage of weathering processes and products, mineralogy of sandstones, cementation and sandstone diagenesis, and sandstone classification. The chapter on cementation and diagenesis is also new and reflects the recent developments in this field which stem directly from petroleum reservoir studies.

Part IV considers the origin, diagenesis and classification of limestones, dolomites and evaporites, while Part V tackles the disparate topics of chert, phosphates, iron-rich rocks and manganese nodules.

The final part is devoted to facies models. Although the nucleus of this section appeared in the first edition, it has been largely re-written and greatly expanded. It emphasizes the predictive nature of facies analysis and environmental interpretation and, although larger than the original version, is still briefer than it should be in view of the importance of accurate facies modelling to economic geology.

There are no attempts at facies modelling using electric-log analysis, which is a pity since these methods are so important in contemporary hydrocarbon exploration. Some diagrams in the first edition were unclear and have been re-drafted, but there are still a few over-reduced diagrams or diagrams taken from poor originals. Yet these are minor quibbles.

Overall, this is an excellent general source text for students and professionals. I hope it appears in paperback — soon.

Bruce Sellwood is a Lecturer in Geology at The University of Reading.

New mineralogy

D. Flinn

Principles of Mineral Behaviour. By A. Putnis and J. D. C. McConnell. Pp.257. (Blackwell Scientific/Elsevier/North-Holland: 1980.) Hbk £18, $45; pbk £9.80, $24.95.

THIS book is the first of a new Blackwell series entitled *Geoscience Texts;* it is also the first new mineralogy textbook for undergraduates to appear for a very long time. Each year a number of ostensibly new texts appear but on examination they turn out to be updated or merely rehashed versions of books which have been with us for decades, or even since mineralogy began. Descriptive mineralogies in one guise or another are legion, and optical crystallographies seem to appear every year, all closely modelled on *Optical Crystallography* by Whalstrom which first appeared in 1943 and now is in its fifth edition (Wiley, 1979). For years I have had to refer my students, for accounts of mineral behaviour, to odd chapters in texts written for physicists, ceramicists, metallurgists and lately geochemists.

Now, at last, such accounts have been put together in one book and brought bang up to date for geology undergraduates. The book is descriptive, being concerned with kinetics rather than equilibria, but the necessary minimum of thermodynamics is clearly and simply presented. The approach is process orientated rather than mineral orientated even though the processes are all demonstrated in common minerals. The authors concentrate on polymorphism and on the sub-solidus behaviour of solid solutions and show how the end products depend more on the time available than on equilibrium relations. I hope that in future publishers will use the resources they now devote to publishing new optical crystallographies to updating this type of textbook and expanding it to cover other types of mineral behaviour such as crystal growth and crystal deformation. □

D. Flinn is Professor of Geology at the University of Liverpool.

Extended senses

Robert N. Colwell

Remote Sensing: Optics and Optical Systems. By P.N. Slater. Pp.575. (Addison-Wesley: 1980.) $34.50, £20.70.

FOR years, remote-sensing educators and their students, as well as engineers and researchers in remote-sensing-related fields, have needed a comprehensive book which would explain, in a readily understandable way, both the principles and the design of various kinds of remote-sensing instruments, and the procedures best used in measuring the performance of such instruments. Professor Slater's book seeks to satisfy that need.

In this book, of 14 chapters and 9 appendices, a systematic treatment is given of the various optical and electro-optical systems that are currently used for remote sensing in the 0.4 to 16μm range, including the Landsat multispectral scanner, return beam vidicon and thematic mapper systems. (Microwave remote sensing — both active and passive — is reserved for another book in the series.) In particular, the author describes in detail the appropriate methods for correcting the "spectral signatures" of features for both atmospheric and system-dependent effects. A substantial amount of the author's own high-quality research is integrated into the book; however its greatest strength lies in the clarity with which Slater has explained, using little more than basic physics and simple mathematics, the relevant work of scientists in a great variety of fields, ranging from human optics to electromagnetic theory, from electronic circuitry to spectroradiometry, and from basic atmospherics to matter/energy interactions at the Earth's surface. Of particular value is his consistent use throughout the book of a powerful performance criterion, the "modulation transfer function".

Despite the prodigiousness of his undertaking, Slater is careful, for the most part, to cite references to the many principles with which his book deals. Thus it is all the more disconcerting when, on occasion, he makes flat assertions (without providing documentation) such as "the average eye can discriminate approximately 5 million colors but only 200 shades of gray". Actually there are almost as many (widely disparate) values quoted in the literature as there are experts who have addressed this highly important matter. An occasional citation is improperly listed in Slater's book but such errors will no doubt be corrected in future editions.

All told, Slater's book is highly authoritative, unusually up to date and comprehensive, clearly written, well fortified with relevant tables and neatly drawn figures, and eminently worth perusal by any serious remote-sensing scientist. ☐

Robert N. Colwell is a Professor at the University of California, Berkeley, and teaches courses in photo interpretation and remote sensing.

Beyond Wiener

Freeman Gilbert

Geophysical Signal Analysis. By E.A. Robinson and S. Treitel. Pp.466. (Prentice-Hall: 1980.) £23.40, $36.

GEOPHYSICAL signal analysis became a subject of research by the authors in the early 1950s, when they were graduate students at MIT. They were members of the Geophysical Analysis Group, sponsored by a consortium of petroleum and exploration companies, whose rather ill-defined goal was to use digital computers for the application of the ideas, techniques and methods of Norbert Wiener to the interpretation of reflection seismograms. In the intervening quarter-century the seismic exploration industry has "gone digital" in a big way. In a typical day the industry processes several thousand computer tapes (9 track, 1600 BPI, 2400 feet) of data on multiple mainframe computer systems. By contrast, in the early 1950s the authors used the Whirlwind II computer (now in the Smithsonian Museum). Input was on punched paper tape, output on electric typewriters and secondary storage on magnetic wire; instruction time was in milliseconds and memory was 1024 16-bit words. It was the premier computer of its day. The authors deserve a large part of the credit for developing many of the currently used computational procedures in geophysical signal analysis and their book provides the basis for understanding and using them. Their firsthand knowledge and experience are evident throughout.

The method of least squares pervades science and engineering; it is the central theme of the present volume. Basically the book is concerned with filtering, the process of removing or diminishing "noise" in order to reveal and enhance the "signal". With the reflection seismogram as a model, the authors develop least squares digital filtering from first principles in the first eight chapters. The subjects of minimum phase lag, minimum delay, causality and stability are presented in a thorough manner, and the concept of a prediction filter is introduced. The writing is well balanced between theory and application. This arises from the blending of the authors' talents — Robinson is a mathematician at home with geophysics and Treitel is a geophysicist at home with mathematics. They complement one another very well.

The second half of the book is devoted primarily to the subject of deconvolution, especially predictive deconvolution. The opening chapter is devoted to a discussion of stationary time series. The method of generalized harmonic analysis, attributed primarily to Kolmogorov and Wiener, is mentioned and briefly described, but the bulk of the chapter is devoted to Wold's predictive decomposition theorem, and deductions from it made by the authors. By using the innovational representation of a nondeterministic stationary time series (that is, the output of minimum delay filter whose input is a white noise process), the authors set the stage for the succeeding chapters on predictive deconvolution. Here, we learn how predictive deconvolution is used to remove multiple reflections and reverberations from seismic traces. The wave propagation theory is the familiar one-dimensional, plane wave theory. It does not conform to the usual common depth point stacking procedures and does not always give good results. The newer slant stacking procedures are better and give more nearly the plane wave stacks for which predictive deconvolution is designed.

The book ends with a chapter on spectral estimation. Both the ARMA (auto regressive, moving average) and ME (maximum entropy) methods are described.

Robinson and Treitel have produced a useful, carefully written book for students, teachers and prospectors. Many of the subjects that they consider are important beyond the realm of seismic prospecting for oil, and their book should find appeal among all scientists and engineers interested in digital signal processing. ☐

Freeman Gilbert is a Professor of Geophysics at the Institute of Geophysics and Planetary Physics, University of California, San Diego. In the early 1950s he was a graduate student at MIT and a member of the Geophysical Analysis Group.

GFD for all levels

D. Anderson

Geophysical Fluid Dynamics. By J. Pedlosky. Pp.624. (Springer-Verlag: 1979.) DM 83.50, $43.90. *Geophysical Fluid Dynamics for Oceanographers.* By J.J. von Schwind. Pp.307. (Prentice-Hall: 1980.) £19.45, $29.95.

THE science of physical oceanography is in the process of emerging from the dark ages, a process begun some 40 years ago and greatly accelerated in the past decade. The companion subject of dynamical meteorology has had a similar history but is slightly further advanced. Together they constitute geophysical fluid dynamics (GFD), an important new discipline which is attracting interest because of its relevance to improving weather forecasts and understanding climate.

With the expansion of the subject has come a demand for textbooks. The two reviewed here are intended for new graduate students or advanced undergraduates, but the levels of the courses for which the texts are suitable are totally different. To the novice student embarking on one of the rather compressed courses which tend to be offered at many institutions, Pedlosky would be rather daunting. Von Schwind, however, is sufficiently elementary that it could be picked up and read profitably by any new student. The subjects discussed in Chapters 3 and 5 are important — wind-driven ocean circulation, the explanation of western boundary currents and some aspects of large-scale wave dynamics — though the presentation could have been markedly improved if some indication of modern thinking had been included (only three of the references are post 1970). Much of the remainder of the book is in the nature of support material. Chapter 2, by far the largest (over half the length of the book), deals with various aspects of basic fluid mechanics and geophysical fluid mechanics. Since many students enter oceanography with no prior knowledge of fluids, this can be quite useful even if much of it is readily available elsewhere.

Pedlosky on the other hand is suitable for more advanced graduate students and specialists. Almost everyone in this category is bound to find something of interest in this intensive book each time he opens it, be it for casual reading or reference. The scope of the book could have been more catholic but the treatment of his chosen material is generally very thorough, one notable exception being equatorial dynamics, an important aspect of modern thinking which gets only marginal coverage in the last chapter (and none at all from von Schwind). The mid-latitude quasi-geostrophic potential vorticity equation is well explained and there is a good section on instability theory. The presentation is mathematically, rather than physically orientated but Pedlosky is a text one can recommend to all serious students of GFD.

D. Anderson is a Lecturer in Atmospheric Dynamics at Oxford University.

Unmathematical air

John Green

Atmospheric Physics. By J. V. Iribarne and H.-R. Cho. Pp.212. (Reidel: 1980.) Dfl. 40, $15.95.

ANOTHER text that is said to require only elementary mathematics — in this case to understand the terrestrial atmosphere. I must confess a bias. To my mind *no* book on physics should use more complex mathematics than is needed to make its point. Conversely, no text should go out of its way to avoid some essential mathematics because the reader may not understand it. He had better be made aware of his deficiency and of the intellectual benefit that will result from being able to understand the mathematical part of an argument.

The authors identify the need for a survey of the physics of the terrestrial atmosphere, suitable for students having completed only one year of a course in general physics. They give a general description of the structure of the atmosphere, atmospheric chemistry, radiation, thermodynamics, cloud physics, and atmospheric electricity and dynamics. Each topic is treated sympathetically but briefly. At the end of each chapter there are questions and problems designed to aid the learning process, and hints on solutions at the end of the book. Diagrams are mostly well drawn but the writing is occasionally careless.

The philosophy of presenting material without recourse to more than elementary mathematics is admirable. Execution is less so. The student is given the appropriate formula with only the most general guidance to the most comprehensive monographs where, I believe, he will find the derivation very difficult to follow. More detailed reference to a text of intermediate standard would help. I think it is useful to comment that a stated formula contains some of the variables you would expect and has a plausible functional form, besides giving a detailed reference to a succinct derivation in the same notation.

This quibble apart, our poor, unfortunate, non-mathematical person will find this a useful, interesting and balanced survey of atmospheric physics.

John Green is Reader in Physical Climatology and teaches a course in atmospheric physics at Imperial College of Science and Technology, University of London.

Star of the lecture theatre

Stephen P. Maran

Discovering the Universe. By Charles E. Long. Pp.511. (Harper & Row: 1980.) Pbk $16.50. *Dynamic Astronomy.* 3rd Edn. By Robert T. Dixon. Pp.523. (Prentice-Hall: 1980.) Pbk £11, $16.95. Teacher's manual also available.

AT A university in southern California, 500 undergraduates in a long, narrow auditorium observe a professor, dimly visible at centre stage, microphone around the neck, lecture on black holes, the Big Bang and life in space. At an East Coast university, a comparable throng files into two adjacent auditoria as the dividing wall between the rooms is electrically retracted; at the same time a large turntable at the front of one of the halls slowly rotates away the entomology instructor who has just finished a lecture. Into view spins the astronomer with demonstration table, microphone and piles of computer-graded examinations that are ready for return to the students. As the lecture begins and the lights fade away, a coloured photograph of a spiral galaxy appears overhead, projected in duplicate to provide identical side-by-side images for the benefit of those sitting at far left and far right in the wings of the assembly.

As the elementary, non-mathematical course in astronomy has become so popular in North America, perhaps 50 competing texts have appeared. The latest, *Discovering the Universe*, is alternately thoughtful and chatty, with many apropos anecdotes and numerous, seemingly-scrawled sketches that are as effective as the usual formal diagrams. At its best (taken on its own terms), *Discovering* introduces the unwary to general relativity with the aid of two inquisitive ants (Einstant and Newtant), or describes Mercury as seen by *Mariner 10*. In the latter case, only a few details are given, but much effort then follows in explaining what one might experience on a visit to the planet. The explanation is clear enough that the student will understand why each prospective phenomenon is anticipated. Marring the otherwise accurate text, however, are erroneous statements (each of which I have seen before) to the effect that *Uhuru* discovered Cygnus X-1 and that the optical pulsar in the Crab Nebula was discovered on the famous Lick Observatory rotating-shutter photographs. Those photos were obtained well after telegrams announced the discovery of the optical pulses at Steward Observatory, their confirmation at McDonald Observatory, and their identification with a specific star — the pulsar — at Kitt Peak National Observatory.

Dynamic Astronomy, here in a third edition, is distinguished by "flip pages", which bear in the margins sequences of diagrams that can be made to spring into life. Riffle them and you will observe Halley's Comet in retrograde motion, tail growing as it approaches the Sun, then shrinking as the comet hurtles back into the far reaches of the Solar System. Other sequences depict planetary, stellar and star cluster motions. Better yet, try turning the same pages slowly and you will find besides the diagrams a well-polished text, familiar by now to the students "in over two hundred colleges and universities". Yet improvements are still to be made. A section on "Observing Meteors" gives the wrong explanation for why more meteors are observed after midnight than before. Contrary to Fig.9-15, globular clusters are strongly concentrated to the centre of the Galaxy although they are more conspicuous in the halo. The sources of the gamma-ray bursts discovered by Klebesadel with data from the *Vela* satellites are confused with the very different "X-ray bursters" studied by Grindlay. Less significantly, although surprising in a mature text, the names of astronomers often are spelled wrong, including those of Olbers, Jastrow, Solomon and Maran. Somehow, when the reviewer's name is misspelled, it always is noticed. □

Stephen P. Maran is at the Laboratory for Astronomy and Solar Physics, NASA–Goddard Space Flight Center, Greenbelt, Maryland.

The Institute of Biology has published a *Handbook for the Animal Licence Holder*, edited by H.V. Wyatt, intended particularly for newcomers to laboratory animal work. The *Handbook* is available from 41 Queen's Gate, London SW75HU, price £2.50 or £2 for five or more copies.

Quantum mechanics for librarians

R. B. Jones

Simple Quantum Physics. By P. Landshoff and A. Metherell. Pp.177. (Cambridge University Press: 1980.) Hbk £12, $29.95; pbk £4.25, $9.95. *An Introduction to Quantum Physics.* By A. P. French and E. F. Taylor. Pp.670. (W.W. Norton/Nelson: 1979.) Hbk $17.95, £15.95; pbk $11.75, £8.95. *Principles of Quantum Mechanics.* By R. Shankar. Pp.612. (Plenum: 1980.) $29.50, £18.59.

AT THE end of any introductory quantum mechanics course, the lecturer sadly concludes that there is not yet a satisfactory textbook while the bemused undergraduate inscribes on the desk top "Schrodinger waives the rules — probably". The three books considered here do not solve the lecturer's problem although each has its merits. They are well produced with a few misprints and each is well provided with problems for which solutions are given at the end of the text. Apart from this they have little in common.

Simple Quantum Physics is based on lectures given at Cambridge University to mathematicians and physicists, and is suitable for a one-term introductory course. I enjoyed reading the book for its brevity and clarity. There is a very brief account of the basic ideas of wave mechanics in which the standard problems are treated up to the hydrogen atom without spin. The mathematical treatment is clear but so concise that only able students will follow what is going on. A short treatment of perturbation theory leads to the most distinctive feature of the book, an excellent introductory account of atomic absorption and stimulated emission and how these can be used to understand a laser. The final three chapters introduce solid-state quantum physics by way of band theory and the physics of real transistor devices. I will recommend this book to our college library and urge my students to read it; however I will use a more detailed text as the required reading in my own course of introductory quantum mechanics.

Out of the MIT Introductory Physics Series comes French and Taylor's *An Introduction to Quantum Physics.* Here the emphasis is on the experimental basis of quantum physics, the coverage ranging from the great historical experiments to modern laser spectroscopy. The basic approach is wave mechanical, although two chapters on photon polarization experiments point the way to the abstract notion of a state vector. All the basic problems up to the hydrogen atom are treated, and both spin and hydrogen fine structure are mentioned. Atomic radiation is discussed although no systematic perturbation theory is included. The mathematical treatment is unfortunately sparse. The student who uses this book will enjoy it, but he will have to do it all again. For that reason I cannot recommend it as a set text in British universities; however, in North America, where there is more time for an undergraduate degree, I would commend it highly for a one-term or one-semester course. Even in Britain many lecturers will want this book for its outstanding illustrations and examples, and libraries should have a copy for students.

Principles of Quantum Mechanics by Shankar is intended for a year-long first course in quantum mechanics. In contrast to the previous authors, Shankar introduces the subject in a loose axiomatic way using abstract linear spaces and the Dirac notation. The attempt to explain the subject at this level means that the book is very long, and even long-winded at times, without covering as much physics as one should expect in 600 pages or so. There are some compensations, however. There is a clear introduction to the Feynman path integral formalism and special attention is paid to the role of symmetries in quantum mechanics. All standard perturbation theory is covered, including fine structure effects in hydrogen. Angular momentum addition is treated and the concept of an irreducible tensor operator is introduced. Scattering theory, electromagnetic field quantization and even the Dirac equation are briefly discussed. This book has merits as a reference book, but I think its place is not in the lecture room. □

R. B. Jones is a Lecturer in Physics at Queen Mary College, University of London.

Approaches to nuclear reactions

James Lowe

Introduction to Nuclear Reactions. By G.R. Satchler. Pp.316. (Macmillan, London/Wiley, New York: 1980.) £23, $59.95. *The Physics of Nuclear Reactions.* By W.M. Gibson. Pp.338. (Pergamon: 1980.) Hbk £19.50, $45; pbk £6.95, $16.75.

BOTH of the authors of these two volumes set out to provide a textbook on nuclear reactions, as opposed to static nuclear properties, for the undergraduate student. Usually, a single book covering the whole of nuclear physics provides adequate detail for an undergraduate course, and several such books are available. There are, in fact, some advantages in having the entire subject in one book — the unity of the subject renders the division into static properties and reactions arbitrary and sometimes confusing. However, the extra detail covered in a specialist book may well be useful to the more inquisitive student, especially if he intends to pursue the study of nuclear physics beyond undergraduate level.

Two books apparently aiming to teach much the same general topic at the same level could hardly be more different in their content and approach. Satchler's book, after an excellent introductory chapter, and an extensive section on basic scattering theory, covers in detail all the theories and models which have formed the basis of our understanding of nuclear reactions over the past 20 years. The treatment is authoritative; many of these models have been developed by Satchler himself. However, the approach is by no means historically orientated — topics of current interest, such as heavy-ion scattering and multi-step processes, are discussed and the book contains plenty of examples of the application of the methods described to "real live" data. The descriptive material is excellent, although curiously the only point at which it is a little misleading is the discussion of the concept of cross-sections, which is sometimes difficult to get across to students. The scope of the book is broad, both in the depth of treatment and in the wide range of topics covered. For example, even Glauber theory, which is useful at energies much higher than those usually encountered in nuclear reaction studies, is described briefly.

By contrast, Gibson's book, which is a new edition of his book *Nuclear Reactions,* provides a much more concise account of the basics of nuclear reaction theories. Unfortunately, several topics which are an essential part of most undergraduate courses are omitted; for example, there is no quantitative treatment of direct reactions. The discussion is clear throughout, and Gibson seems sometimes to assume a more elementary starting point for his readers than does Satchler. Gibson provides an excellent discussion of particle accelerators (though not of any other aspect of techniques — a curious selection), and also gives an account of the physical principles of fission and fusion reactors. His final chapters on nuclear forces and nuclear spin give good accounts of these topics, with a breadth of treatment beyond that directly relevant to nuclear reactions.

The choice between these books for the student must be based on their content. The student who intends to concentrate on pure nuclear physics will find Satchler's treatment valuable, and the content of this book will be useful well into the student's postgraduate years. In fact, the treatment is sufficiently extensive and not too elementary for many research physicists. For the student who intends to move towards applied nuclear physics or energy research, especially if involved in the physics of reactors, Gibson's book may be the more relevant. □

James Lowe is Senior Lecturer in Nuclear Physics in the Department of Physics, University of Birmingham, UK.

Astrophysics

R.J. Tayler

The Physics of the Interstellar Medium. By J.E. Dyson and D.A. Williams. Pp.194. (Manchester University Press/Halsted: 1980.) £11.95, $24.95. *Radiative Processes in Astrophysics.* By G.B. Rybicki and A.P. Lightman. Pp.382. (Wiley-Interscience: 1979.) £16.95, $39.85.

ASTRONOMY, as well as being an exciting subject in its own right, gives a student an excellent opportunity to see how different branches of physics are brought together to solve a particular problem. For that reason, stellar structure, which involves atomic and nuclear physics, thermodynamics and statistical physics, electromagnetism, fluid dynamics and gravitation, is a popular option for physics undergraduates. The physics of the interstellar medium provides another excellent example of the interplay of different branches of physics and chemistry, such as the origin and transfer of radiation throughout the electromagnetic spectrum, hydrodynamics and magnetohydrodynamics and the physics and chemistry of small particles and molecules. Although it is a good subject for an undergraduate course, there is a lack of suitable textbooks. There is one outstanding book, *Physical Processes in the Interstellar Medium* by L. Spitzer (Wiley-Interscience, 1978), but this is far too advanced for the average or weak undergraduate.

The book by Dyson and Williams is written for the undergraduate audience and contains a range of topics which almost exactly matches the lecture course given to third-year undergraduates at Sussex. To some extent there is emphasis on the research interests of the two authors, interstellar hydrodynamics (Dyson) and interstellar grains and the formation and destruction of molecules (Williams), but overall it gives a good impression of the range of physical problems met in the interstellar medium. It is clearly written and contains a useful number of examples, and, as it uses SI units, it should be immediately intelligible, at least to UK undergraduates. It is a pleasure to be able to recommend to my students a book at a level suitable for all of them.

Rybicki and Lightman are also concerned with astronomy as physics but instead of dealing with a particular branch of astronomy they have considered all astrophysical applications of one branch of physics, the origin and transfer of radiation which is of particular importance in the interstellar medium. This is an outstanding book which has reached me when I am preparing an MSc course on the subject. It is making my task both simpler and more enjoyable, although I regret the need to translate its formulae from cgs to SI units.

Rybicki and Lightman have covered a wide range of topics, including the fundamentals of radiative transfer and a review of both electromagnetism and special relativity as well as discussing the various types of radiation from free particles (bremsstrahlung, synchrotron and inverse Compton radiation) and atomic and molecular structure and spectral lines. They have succeeded admirably in giving all the necessary information without too much unnecessary detail and the book contains many problems with worked solutions. The book should be of wide general interest to physicists as well as astronomers, since only the problems are specifically astronomical, and I hope that its title will not prevent them from recognizing its value. □

R.J. Tayler is Professor of Astronomy at the University of Sussex, managing editor of Monthly Notices of the Royal Astronomical Society *and author of three introductory astronomical textbooks.*

Facets of thermal physics

P. T. Landsberg

Principles of Thermodynamics. By J. A. Beattie and I. Oppenheim. Pp.329. (Elsevier Scientific: 1979.) Dfl. 98, $47.75. *Thermal Physics.* 2nd Edn. By C. Kittel and H. Kroemer. Pp.473. (W.H. Freeman: 1980.) $22.95, £11.30. Instructor's manual also available.

THE images of joint authors BO and KK (for short) transmitted by these two interesting and worthwhile books are rather different. BO (viewed as a unit) dresses in a formal dark suit, is reliable, a trifle old-fashioned and, because of a personal communication of 1911 acknowledged in the text (p.170), not a hot-headed youngster by any means. He has a good sense of the history of the subject: nineteenth century references are frequent, and only one or two literature citations from the 1970s occur — "new-fangled stuff compared with Clausius and Joule" one hears him say. He likes open systems and chemical potentials: van't Hoff's equilibrium box is not often discussed. Indeed there is an interest in fundamentals: Carathéodory's principle, the unattainability principle, Gibbs paradox are all considered though the commentaries and developments of these topics in the 1970s are not touched on. "Too new" said the author, replacing his pince-nez.

KK, on the other hand, wears a sports jacket and jeans, is most excited by newer developments, and readily departs from general principles to discuss effects and applications in this (largely rewritten) second edition: superconductors, solar constant, Overhauser effect, p-n junctions, heat pumps and particle–antiparticle equilibrium are all noted. Some of these interesting things are, however, in the problems. "Come on boys, this is fascinating stuff, you can do it", he says, while writing his concluding piece on negative temperatures. But there must always be a doubt on that point. An author may not even be able to solve his own problems if he has left the subject for a while.

If our authors should meet, one can imagine BO asking KK "Why is Nernst not mentioned or unattainability or Pfaffians?". "Well, there are special books for that" answers KK, puffing at his pipe; "Why don't you write one like that?". "I have" says BO.

Knowing some of the authors, the appearances inferred from their books are actually quite wrong. But the point is clear: thermal physics is a many-faceted subject and to get the full flavour it may not be enough to read one book. Even two, the above two, lucky though one is to have them, may not be enough. One would have to go elsewhere to learn about negative heat capacities, Saha's equation or black-hole thermodynamics.

This is not the place to make criticisms of details, but it may be of wider interest to note the following point (taken from my own book on the subject), which neither author stresses though they both deal with the zeroth law of thermodynamics. This law is $(A \equiv B, A \equiv C) \Rightarrow (B \equiv C)$. It states the transitivity of thermal equilibrium (denoted by $\equiv$), A, B and C being systems. Now comes a question which in its simplicity is suitable for the promotion board of the Scientific Civil Service: does the existence of a single temperature function follow, such that temperature equality and thermal equilibrium is the same? The answer is "No". This may be seen by interpreting "$\equiv$" as the condition for parallelism of lines, A, B, C in space. This requires *two* angles which specify the directions of the lines to be equal. Hence we have shown that cases exist in which a single function is inadequate. □

P. T. Landsberg is Professor of Mathematics at the University of Southampton.

Introductory . . .

W. Cochran

Elements of Solid State Physics. By M. N. Rudden and J. Wilson. Pp.186. (Wiley: 1980.) Hbk £14.50, $40; pbk £5.95, $17.

CHARLES Kittel maintains that "One test of a solid state course is that it should treat holes correctly". The book under review fails this test, since the authors cheerfully discuss the Fermi level in terms of the water level in a flask, a hole in terms of a bubble in the water, and that is almost their last word on the subject. However this is not meant to be a book for professional physicists, who will (perhaps) know that the wave vector of a hole state is *minus* the wave vector of the corresponding unoccupied electron state, a fact that cannot be of much interest to an engineer designing a large-scale integrated circuit. The authors are not lacking in ambition, for they have set out to write a textbook for the student who requires to be introduced to the Bohr model of the hydrogen atom on p.15, and who is yet presumed to be ready to understand the physics of the tunnel diode by p.153 — they are writing for

> the increasing number of students studying solid state physics at an introductory level, many of whom require only sufficient background to understand the operation of modern solid state electronic devices.

I began to read the book with some scepticism but I became increasingly impressed by the ability of the authors to convey ideas by means of arguments and analogies which, although they do not treat each concept "correctly", are almost always helpful and will not have to be consciously unlearnt by the student who goes on to study the subject more deeply. Once or twice I thought the authors were unhelpfully wrong, as when they write on p.87 that "for an intrinsic semiconductor at absolute zero the Fermi level coincides with the top of the valence band", then continue on p.88 with an unconvincing reason for its being "halfway between the two bands", and finally on the same page give a valid argument why it "can perhaps be best understood" to occupy the latter position.

All in all, the authors are to be congratulated on their success in writing a non-mathematical book on solid-state physics which is genuinely an introduction. Possibly students of electrical engineering need not know more than this about solid-state physics *per se* but, if they must, they will find several other books in the reading list, including inevitably Charles Kittel's *Introduction to Solid State Physics* (5th Edn, Wiley, 1979), which is close to the other end of the spectrum of introductions. □

W. Cochran is Professor of Natural Philosophy at the University of Edinburgh.

. . . and applied solid-state physics

J. C. Anderson

Introduction to Applied Solid State Physics: Topics in the Applications of Semiconductors, Superconductors, and the Nonlinear Optical Properties of Solids. By R. Dalven. Pp.330. (Plenum: 1980.) $27.50, £17.33.

THE philosophy of this book is that solid-state physics teaching, in physics courses, often lacks reality — a view with which I would not disagree.

The book is based on a lecture course, given by the author in the Department of Physics at the University of California, Berkeley. The course evidently set out to *survey* the *physics* involved (author's italics) in a variety of solid-state devices. To this end, the first two chapters rapidly review basic semiconductor physics and the p–n junction, giving liberal references to *Introduction to Solid State Physics* (5th Edn, Wiley, 1979) by Charles Kittel (who apparently encouraged the author to develop his course) and other relevant texts. The following chapters then deal with semiconductor devices such as the transistor (both bipolar and field effect), metal–semiconductor junctions and their applications such as Schottky diodes, and the present generation of devices available through MOS technology. A chapter devoted to other semiconductor devices is something of a rag-bag and rather unwisely attempts to encapsulate the physics of amorphous semiconductors in four pages. In this fast-moving field such an attempt is decidedly unwise. However the day is always saved at the end of each chapter by a suggested reading list and references to key papers, which should enable the reader to overcome any shortcomings of the exposition. The remaining three chapters deal with generators and detectors of electromagnetic radiation, superconductive devices and materials and, finally, nonlinear optical properties of solids.

Essentially, the book is offering itself to lecturers wishing to illuminate their solid-state physics teaching, and to those students who might have sufficient curiosity about the relevance of their solid-state physics course to go and read a book. In this context the book succeeds, as evidently did the author's lecture course. In a wider context it is also useful as a quick reference guide to a scientist or engineer wishing to remind himself, or learn for the first time, of the basic physics behind a device with which he has to deal. It successfully dispels, *inter alia*, the delusions that a squid is a kind of cuttle fish or that the Josephson junction is a crossroads near Bethlehem. □

J. C. Anderson is Professor of Electrical Materials in the Department of Electrical Engineering, Imperial College of Science and Technology, University of London.

Electromagnetism, old and new

John Pain

Electricity and Magnetism. 3rd Edn. By W.J. Duffin. Pp.467. (McGraw-Hill: 1980.) Pbk £7.50, $18. *Fundamentals of the Theory of Electricity.* By I.E. Tamm. Pp.684. (Mir/Central Books, London: 1980.) £6.95.

FORTY years separate the first editions of these two books yet the essential contents are common to both. Most topics in physics advanced beyond all recognition during this particular period but the foundations of electricity and magnetism, as laid by the scientists of the nineteenth century, remain definitive.

Tamm is one of the great names of Russian physics; here an engaging slip in the biographical blurb awards him the Noble (*sic*) Prize. His book was first published in 1925 and ran to eight editions with only minor amendments before he died in 1971. His final preface acknowledged the need for a major revision but the ninth edition, published after his death, left the work unchanged. The book under review is a translation of that posthumous edition and the preserved style of the original anchors it firmly in the period of the inter-war years. This will commend it to a diminishing group of readers — those with a sense of history and a nostalgia for the European teaching tradition of that time. A lucid translation and good Romanian printing may encourage a wider audience but the theoretical bias, unrelieved by reference to practice, plus the use of an unfashionable system of units, will make no appeal to the physics undergraduate who has grown up in the world of radio, television, computers and communication satellites.

When Tamm first wrote this book radio was still in its infancy and he was under no pressure to include those experimental details which illustrate the extraordinary power of electromagnetic theory. An unrevised version of the same book is difficult to justify in 1981.

If Tamm's is the work of a past master, Duffin's is a model of what a modern textbook should be. The third edition deserves to be even more successful than the first two, for the author has expanded some of the more advanced topics and revised his presentation, helped by imaginative typography. This really is a book for all physics students (and course lecturers). The basic theory is there but solid physics flesh covers the mathematical bones without running to the fat of an over-written text. The book covers the first two years of an honours course in a British university and Duffin's technique is to take the early chapters slowly and to accelerate when the student is well grounded. His concern not to lose the reader is shown by commentaries and by revision summaries at the end of each chapter which bring the preceding pages into sharper focus. In addition there are nearly 300 problems and the answers are given to all of them with many useful hints.

There are few books which leave the impression that an outstanding lecture course has been transferred from blackboard to page — this is one of them. ☐

John Pain is Reader in Physics at the Imperial College of Science and Technology, University of London.

Learning soil physics

David L. Rimmer

Soil Physics. By T. J. Marshall and J. W. Holmes. Pp.345. (Cambridge University Press: 1980.) Hbk £33, $77.50; pbk £10.95, $21.95. *Applied Soil Physics: Soil Water and Temperature Applications.* By R. J. Hanks and G. L. Ashcroft. Pp.159. (Springer-Verlag: 1980.) DM 39.50, $22.20.

FOR some time an alternative has been required to the standard text on soil physics, *Soil Physics* by Baver *et al.* (4th Edn, Wiley, 1972), especially as it never appeared in paperback and eventually became too expensive for undergraduates to buy. The book by Marshall and Holmes is thus to be welcomed. In it they present a full account of the subject, concentrating in the first half on fundamental and theoretical aspects, especially of soil water, and in the later chapters dealing with the more field-orientated or management aspects, for example structural stability, compaction, tillage and irrigation.

The material is readable and attractively presented; tables and figures break up the pages, avoiding the problem of page after page of continuous text interspersed only by intimidating equations. Throughout there are many references; about 600 in total, these are brought together at the back of the book to provide a most useful reference list. There are, however, certain inconsistencies between chapters. For example, in Chapter 2 the total potential of soil water is defined in terms of pressure, osmotic and gravitational potentials only, where pressure potential is taken to cover matric potential under certain conditions. In Chapter 12 the total potential of water in plants is defined in terms of all four potentials separately. The choice of symbols and the use of SI units is generally good. Units for density however cause some problems; these appear in different places as kg m^{-3}, g cm^{-3} and Mg m^{-3}. Yet these are relatively minor criticisms of what is a very good book, which should become widely adopted.

Applied Soil Physics by Hanks and Ashcroft is different in many respects, although aimed at a similar readership (students of soil physics and scientists in related fields). First, its scope is more limited, as suggested by its sub-title *Soil Water and Temperature Applications.* Second, it specifically aims to show how the basic theoretical equations can be applied to field situations by means of numerous worked examples. These examples are backed up by sets of problems at the end of each unit (chapter). The aspects of soil water are dealt with in four units and soil temperature in a final unit. By working through the units the physical significance of the rather abstract theoretical relationships is made more apparent. The book is not strictly a textbook, but then it was not intended to be such (as evidenced by references to relevant textbooks at the end of each unit). What the book offers is an aid to teaching the subject. Its usefulness as such is somewhat diminished by the use of non-SI units, which may cause problems for students. But as a source of worked examples and relevant problems it will be of value to teachers of soil physics. ☐

David L. Rimmer is a Lecturer in the Department of Soil Science at the University of Newcastle upon Tyne.

Pedology illustrated

Milo I. Harpstead

Soils: Their Formation, Classification and Distribution. By E.A. FitzPatrick. Pp.353. (Longman: 1980.) £25, $60.

SOIL science has attracted increased public awareness in recent years and has become the professional concern of scientists in a wide variety of fields. Soils can be lost by erosion and contaminated by pollutants, sometimes with disastrous consequences, and vary in their suitability to produce crops, support structures and accept waste products. Soils are being inventoried on a world-wide scale and soil survey reports are now consulted for purposes of land-use planning.

This book covers a wide range of topics

text books

MACMILLAN
PRESS

ORBITALS & SYMMETRY
D. S. URCH
This book introduces both symmetry and molecular orbital theory in one volume. The mathematics which chemists need to apply to symmetry ideas is developed using molecular examples, (rather than abstract mathematical ones). At all stages worked problems are given in the text and further exercises are set at the end of each chapter.
The aim has been to give the reader a critical appreciation of two very important aspects of theoretical chemistry, molecular orbital theory and symmetry, and to show him how to apply them to a wide range of chemical problems.
£4.95, 0 333 26675 7

CHEMISTRY FOR THE LIFE SCIENCES
Second Edition
J. C. DAWBER and
A. T. MOORE
The book is primarily designed as an integrated chemistry text for undergraduate students on degree courses in biology, biochemistry, pharmacy, and medicine at universities, polytechnics, and colleges of higher education.
It will also serve as a text for HNC and HND students in Applied Biology and Medical Laboratory subjects, and students studying for MIBiol. and Membership of the Institute of Medical Laboratory Technicians. Students on joint honours courses (e.g., Combined Science) in which biology is a major subject will find the book useful.
£16.00, 0 333 25820 7
£8.95, 0 333 25821 5

PLANT METABOLISM
H. D. KUMAR and
H. N. SINGH
The highly complicated, interconnected metabolic cycles that continue unceasingly within the living cells of plants are refreshingly simplified in this classic text for students of botany and those studying agricultural botany and plant physiology in agricultural colleges.
The physiologist, the biochemist, and the phytochemist – each will find his particular field ably covered in this masterful analysis which integrates the different features of plant chemicals – their potential functions, their synthesis and degradation – into a comprehensive account.

M MACMILLAN PRESS

normally taught in undergraduate courses. It is well illustrated with excellent photographs and drawings; of particular interest are the illustrations of landscape–soil relationships for several climatic regions of the world and the numerous photomicrographs from thin-sections showing the soil micromorphology resulting from the processes being described. In addition, there are 16 colour plates of soil profiles, representing major soil regions of the world, and a number of tables which represent an exhaustive compilation of information from international sources.

However, the book does have its faults. Mr FitzPatrick has reviewed the world literature on soils, but surprisingly he seems to have missed the point in his critical assessment of Hans Jenny's opinion about the factors of soil formation. Less importantly, he cites secondary sources for the theories of Davis and Penck on slope development, giving the impression that they were formulated several decades later than they were.

Many authors have developed their own nomenclature similar to that of Mr FitzPatrick; such terminology is usually short-lived and confusing if it does not reflect broad acceptance within the discipline. The author reminds us that soils form a continuum in space and time and that "this situation defies classification". He contends that for 80 years pedologists have tried unsuccessfully to construct a satisfactory hierarchical system of soil classification and this leads him to conclude that it simply cannot be done. The USDA uses the most elaborate hierarchical system in the world and so receives Mr FitzPatrick's severest criticism, an assessment which is contentious, to put it mildly.

This is a valuable book for pedologists, but has limited value for students who are attempting to master an established system of soil nomenclature and classification. □

Milo I. Harpstead is Professor of Soil Science at the University of Wisconsin, Stevens Point, and the author of Soil Science Simplified *(Iowa State University Press, 1980.)*

All round food production

J. C. Bowman

Agricultural Ecology: An Analysis of World Food Production Systems. By G. W. Cox and M. D. Atkins. Pp.721. (W. H. Freeman: 1979.) £15.70, $29.95.

A RIGOROUS analysis of world food production systems involves an understanding of many aspects of science and social science. One method of teaching agriculture is to consider the relevant disciplines of chemistry, biology, economics and so on, and then gradually to bring this knowledge together to show how it relates to food production systems adopted on farms. Undoubtedly this approach tests the patience of students and requires them to have faith that those aspects of science and social science which they study are relevant and will eventually interrelate to give a sound understanding of agriculture. Students can gain confidence and make a more purposeful approach to the choice of constituent subjects if they have an overview of agriculture from the start of their studies.

Cox and Atkins have made a brave and largely successful attempt to provide such an overview by considering agriculture as a group of ecosystems. Their book is in three parts. The first deals with the ecological and historical context of agriculture, the second with the dynamics of agroecosystems and the third with agriculture and the future. For a text with such a wide range of subjects which require integration and focus there is a big advantage in the easy and consistent style which the authors have achieved. There is a great deal of quantitative material which has been made comprehensible, even enjoyable.

It is perhaps inevitable that with only two authors some imbalance of subject matter has arisen. In particular there is considerable emphasis on agricultural pest problems — nearly half of Part Two is devoted to this topic — and there is much more attention given to crop rather than livestock production systems. This may represent, albeit inadvertently, the authors' view of the future importance of these subjects. A stronger element of the anthropological and sociological aspects of agriculture throughout the world, particularly in appreciating changes in agriculture in the developing world, would have been beneficial. Even so, the text gives a good account of the ecological approach to agriculture.

The book is profusely illustrated with photographs, diagrams and tables. Some of the diagrams have a minimum of explanation and in several cases students will need to return to the source for a full appreciation of what they portray. Each chapter has a good bibliography which draws heavily on American literature, and contains relatively little reference to publications after 1976 even though the book was not published until 1979.

The book should be valuable to all students of food production systems throughout their course. A text to be read and re-read as a student gains knowledge of the constituent parts of the subject. □

J. C. Bowman is Director of the Centre for Agricultural Strategy at the University of Reading.

Conserving resources

Ronald F. Hensler

Soil and Water Conservation (For Productivity and Environmental Protection). By F.R. Troeh, J.A. Hobbs and R.L. Donahue. Pp.718. (Prentice-Hall: 1980.) £16.85, $25.95.

THE first two chapters of this readable and well-edited book give an historical as well as a world-wide perspective on soil erosion. As well as providing students with a broad view of their subject, they should be required reading for those making decisions which in any way determine how land will be used, and thus to what degree that land will be subject to erosion by water and wind.

With the principles laid down, the authors go on to evaluate the parameters involved in water and wind erosion forces and soil-loss predictions. References here, as throughout the volume, are a useful combination of the key original concepts, recent research, and review articles.

Chapters 8, 9, 10 and 12 cover soil and plant management and conservation structure techniques (tillage, cropping systems, terraces, dams and so on) that can be employed to reduce erosion. Critical design requirements as well as discussions of the pros and cons of each technique are provided. The remainder of the book deals with soil surveys and land-use planning, mine and construction site reclamation, pasture, range and forest management, water conservation, drainage, irrigation, soil and water pollution, economics, United States soil and water conservation agencies, and conservation around the world.

Other features include a summary, (though not of the thought-provoking variety), and references at the end of each chapter. The illustrations are appropriate, and the subheadings have been well planned with each subsection able to stand by itself so that a teacher can assign portions of chapters without losing the integrity of the whole.

The major difference between this and other books on soil and water conservation is that most textbooks are engineering-orientated to meet the on-the-job needs of a practising soil conservationist. This book, then, is particularly welcome in filling a gap.

Soil and Water Conservation should certainly be considered for adoption by teachers of soil and water conservation courses. In addition, it will be a useful reference book for all agronomists, all politicians and all who make decisions that affect land use. I only hope such people read it. □

Ronald F. Hensler is Associate Professor of Soil Science at the University of Wisconsin, Stevens Point.

Darwin's death in South Kensington

What is the British Museum (Natural History) for? Research? Public enlightenment, even entertainment? Or should it be, as Dylan Thomas said in another connection, a "museum that should be in a museum"? In spite of the stream of correspondence in the past several months, itself a measure of the museum's claim on public esteem and even affection, we are none the wiser. The museum, now at the beginning of its centenary year, has not replied to the several issues which have been raised since Dr Colin Patterson's cool comment on the role of cladistics in taxonomy (*Nature* **288**, 430; 1980). Halstead (this issue, page 742) is right to draw attention to this deafening silence.

The issues are not, after all, so complicated. Cladistics is a technique used in systematics for the classification of organisms that may or may not belong to distinct species. Cladism, of which Halstead is a well known enemy, is presumably the belief that cladistic analysis yields meaningful results. Halstead's original complaint against the museum was that a new public exhibition at the museum on "fossil man" is shot through with cladism to such a degree that familiar relationships between fossil human forms are obscured, which only went to show that the museum had been captured by Marxist ideology. The second charge, always a red herring, cannot be sustained. The public face of the museum is trendy, not revolutionary. The questions which have been raised, and which the museum must in the public interest answer, are not nearly as grand but are, by the same test, not so easily ignored.

Even the row there has been about cladism in public exhibitions is probably only a symbol for a more mundane but more important discontent — the museum's exhibition policy that has been evolving for the past five years or so. Waterhouse's Victorian pile has been a hive of activity throughout that period. The dinosaurs and stuffed birds have taken a back seat, or have been hidden away in back rooms, to make way for much more jazzy exhibitions. Although some of these are second-rate (that on ecology), simple inspection shows that others (that on human biology, subtitled "An exhibition of ourselves") fascinate and delight the crowds of visitors, many of them young, who are forever pressing buttons to provoke yet another physiological model into action. Nobody disputes the public demand for this kind of exhibition and there is even a possibility that it may assist in the education of the young and the general public. The practical issue is whether the museum should be encouraged, or even allowed, to fill itself with "exhibits" designed to "present the whole of modern biology" when the acknowledged consequence will be the replacement of "almost all" of the existing exhibitions.

This quarrel has been simmering for a long time, but the museum's dilemma is not negligible. Its postwar managers inherited a labyrinth of poorly lit galleries in which specimens of various kinds were so crammed together that their identity could hardly be discovered, especially if the ink had faded on the labels. The choice was to make the existing exhibition intelligible or to embark on a more ambitious policy. In 1972, when the pressures on public funds were magically almost imperceptible, the die was cast and the decision taken to remodel the whole museum. Since then, the museum has been constantly in hot water over its building plans. (The latest scheme for rebuilding the back of the museum, in the process changing the outline and the roof profile, confirms the suspicion that only public authorities can now commit vandalism openly.) Two questions persist. It there is a public need in London of a popular museum of science, why should its creation mean the end of the more scholarly exhibition created by the Victorians? The truth is that there is a need for both. And if the museum is irretrievably launched on its new policy of public education, how sensible is the course it is following?

The museum's showing so far is not encouraging. The latest brochure from the museum starts from the view that learning should be enjoyable. There is nothing wrong with that, even though the repetition of the jingle "learn and enjoy" may make many serious teachers wince. The danger, which many popular museums of science have discovered, is that enjoyment often interferes with learning. Pressing buttons to make things happen is an absorbing occupation at most ages, but is not by itself an educative process. In reality, the new exhibitions at the Natural History Museum, novel though they are for central London, differ only in scale from others to be found elsewhere in the world. It would be easier to believe that the museum is embarked on a worthwhile course if there were signs that it had seriously set out to break new ground in the public exhibition of science. Is it too late to look for signs of redemption in this respect? The new exhibitions promised for the summer may provide some clues.

The charge that the museum's new exhibitions are shot through with heresy, overstated though it may have been, also needs to be answered more categorically than in the past few weeks. Again there is right and wrong on each side. In the latest brochure, the popular euphemism for cladism is the phrase "the groups-within-groups classification", presumably a synonym for species. There is also the following passage: *Biologists try to reconstruct the course of evolution from the characteristics of living animals and plants and from fossils, which give a time scale to the story. If the theory of evolution is true* . . . If the words are to be taken seriously, the rot at the museum has gone further than Halstead ever thought. Can it be that the managers of the museum which is the nearest thing to a citadel of Darwinism have lost their nerve, not to mention their good sense? Or is it that somebody has calculated that the museum will increase its annual intake of visitors by enticing in scoffing creationists?

This passage nicely illustrates what has gone wrong at the museum. The new exhibition policy, the museum's chief interaction with the outside world, is being developed in some degree of isolation from the museum's staff of distinguished biologists, most of whom would rather lose their right hands than begin a sentence with the phrase "If the theory of evolution is true . . ." Nobody disputes that, in the public presentation of science, it is proper whenever appropriate to say that disputed matters are in doubt. But is the theory of evolution still an open question among serious biologists? And, if not, what purpose except general confusion can be served by these weasel words?

The most urgent need at the museum is to restore the once close relationship between the museum's scholarship and its external face. It is demeaning that many of those working as scientists at this distinguished place should not have been persuaded to harness their scholarship to the brave new policy. No doubt, if they had been more closely involved, the pace of development would have been slower and the museum might have been dissuaded from its promise to put "the whole of modern biology" on display. That, if the managers think about it, would be an advantage. For all its distinction, the museum is not equipped for such a task. What it can do well, as in the past century, is to tell the absorbing tale of natural history. It should bend its mind to that, not to worrying about cladisim.It should beware of selling out on Darwinism. And it should say, from time to time, what it is about. Hitherto, the museum has been too secretive.

New Pentagon rules on overseas students

Secrecy threat to sensitive research plans

Washington

Restrictions on the use of foreign research students on non-classified research projects sponsored by the Department of Defense are in the offing. This prospect stems from the requirement, recently emphasized by Congress, that the multi-million dollar research programme sponsored by the department in very high speed integrated circuits should be strictly controlled to prevent the export of technical data of potential military value.

Pentagon officials say they are "bending over backwards" to minimize interference with the freedom of university research in applying controls. These controls were introduced in 1972 as the International Traffic in Arms Regulations (ITAR) to cover the export of unclassified technical data. Many academics, however, see a danger of renewed threats to academic freedom previously raised by secret military research on university campuses.

Because of the uncertainties which abound, the Defense Department has issued guidelines to both universities and private contractors carrying out sponsored research on integrated circuits. Where research can be classified as "process development" and is likely to lead to a specific improvement of military technology, controls will apply and it will be necessary to obtain an export licence from the State Department before the research is even discussed with a foreign citizen. But where the research can be classified as the "general pursuit of knowledge", with no particular application in mind, then controls will not apply.

Pentagon officials admit that there is a "grey area" dividing the two, particularly in materials science research and other areas closely linked to improving the efficiency of semiconductor systems. The Defense Department has told universities of its "preference" that foreign students should not be employed on integrated circuit programmes, but that the programme office will "make a decision based on the nature of the research" where restraint is not feasible.

The consequences could be significant. The proportion of foreign research students in US universities has risen dramatically in the past few years to about 50 per cent — and is particularly high in fields such as computer science, where first degree graduates can command large salaries in the private sector.

Several universities are concerned that strict interpretation of the regulations could reduce flexibility in research programmes, especially since the Department of Defense is the major supporter of this line of research. There is also mounting anxiety that the regulations might be abused. They are written so broadly that it is a federal crime to discuss with a foreign scientist any research result which might improve the "state of the art" of US military technology without prior approval by the State Department.

These fears have been reinforced by the National Security Agency's attempts to restrict the dissemination of cryptography research results obtained by Dr George Davida of the Georgia Institute of Technology (see *Nature* 19 February, p.621). Integrated circuit research is less sensitive, but government officials could theoretically use the regulations to close down semiconductor research in universities, on the grounds that, almost by definition, such research must advance the state of the art.

Commercial contractors for the Defense Department are also worried, since a strict interpretation of the regulations could prevent them from communicating research data, even if unclassified, to overseas affiliates.

The Defense Department, well aware of such objections and keen to avoid fresh campus confrontations such as those during the anti-war demonstrations of the 1960s, hopes that its new guidelines will convince universities of its concern for the freedom of research. Its proposals have been circulated through the Association of American Universities, a group of top US research universities, and will be discussed at a meeting of university and government officials in Washington next week.

Faced with other financial problems, universities are keen not to rock the boat by rejecting the new requirements as unreasonable. But many are wary of what they are letting themselves in for — hoping that it is not the thin end of an increasingly sticky wedge. **David Dickson**

British gene company opens books

Britain's national biotechnology company, Celltech, has begun marketing its first product: the monoclonal antibody to leukocyte interferon which, fixed to beads in a fractionation column, can purify interferon 5,000-fold in a single step. But since the discovery (see *Nature* **285**, 446-458; 1980) fell before November 1980, when Celltech negotiated rights to Medical Research Council biotechnical inventions, the National Research Development Corporation will retain a slice of the action. Profits on sales will be divided between Celltech, the corporation and the council.

The researchers who created the cell line, Dr David Secher of the MRC Laboratory of Molecular Biology, Cambridge, and Professor Derek Burke of the University of Warwick, also stand to gain but by different routes. In Burke's case, the standard revenue-sharing agreement will give the University of Warwick half the development corporation's profit; and Burke and colleagues in his laboratory will receive half of that, less the university's costs in running the laboratory for the relevant period. Secher, on the other hand, must look to his employer, the Medical Research Council. The council's agreement with Celltech allows for some reward for the researcher, but it is not clear at this stage how much. There is a standard arrangement for "inventors" in which a joint council-corporation panel meets every three years (the next meeting is in December 1982) to distribute largesse to those who have contributed to the council's coffers by work "outside normal duties". (In 1979, £130,000 was distributed to 30 inventors in amounts ranging from £40 to some thousands of pounds.) The catch is that many commercially valuable inventions — like monoclonal anti-interferon — fall within normal duties, and so in principle outside the inventors' scheme. Nevertheless, the council says it will interpret the phrase liberally in future.

In the end, the central issue is not how the loot will be divided but whether there will be any loot at all. The council hopes that the fledgling and hungry Celltech will be more assiduous than its traditional partner, the National Research Development Corporation, in exploiting inventions. Proposals are already in hand with a number of potential customers interested in the purification and radioimmunoassay of interferon using the antibody. However, Hoffmann la Roche is also believed to have developed similar cell lines, so there may be commercial competition.

Then the question will be how good is the Celltech line? There is more than one kind of interferon, and Celltech's antibody is strictly an antibody to a single interferon, one from the group of interferons supplied by the Wellcome Laboratories (consisting of 8 to 16 proteins) which formed Burke and Secher's starting material. Nevertheless, says Burke, evidence is accumulating that their antibody will bind to similar sites in a number of related interferons, so its specificity may not be unduly narrow. The initial quantities of antibody will be produced in Cambridge. Ultimately production will move to Celltech's new laboratories in Slough. Celltech expects a modest market for interferon for clinical trials over the next few years, with the promise of a much larger market if interferon proves to have therapeutic value.

Robert Walgate

0028-0836/81/090736-01$01.00

Celltech's deal with MRC

The Medical Research Council revealed last week the broad outlines of its five-year agreement with Celltech, signed on 6 November last. The agreement raises perturbing prospects of delays in the disclosure of scientific information. It concerns work done by researchers directly employed by the council and not that of its grant-holders employed by universities.

The council has undertaken to inform Celltech of commercially interesting discoveries by its researchers in fields related to biotechnology before the work is published. (In other fields, the traditional relationship with the National Research Development Corporation will be maintained.) The council says that the freedom of its research workers to communicate with other academic scientists will not normally be impaired, but occasionally publication would have to be delayed "for a short period" while a decision is taken on patenting.

Dr Sydney Brenner, director of the Laboratory of Molecular Biology and a member of Celltech's Science Council, is unconcerned. Delays will not be serious, and the issues involved are less difficult than those which arise when individuals have links with commercial companies.

In return for the right to information (and ultimate exploitation), Celltech will give the council a "substantial proportion" of any royalties or profits that ensue. The council will place this money in a separate "Celltech fund". When the fund reaches a sensible level, a subcommittee will call for proposals from both universities and council establishments on how it should be spent. In the early stages, when the fund is limited, grants will be restricted to fundamental research in areas related to biotechnology. If the money rolls in, the scope of the fund will be widened.

If, however, the sum in the fund rises beyond a fixed limit, which has been agreed between the Department of Education and Science and the council, but which neither will reveal because of its quasi-commercial nature, the dispensation that allows the council to accept money from Celltech will have to be renegotiated. Hitherto, the arrangement between the research councils and the development corporation has been that the research councils can receive no such payment. **Robert Walgate**

Polish universities

Sit-in complete

Last week, Poland's month-old student sit-in in Lodz ended with the signing of a wide-ranging agreement on academic autonomy. The students' action had begun over alleged delays by the Ministry of Science, Higher Education and Technology in registering the new Independent Students' Association (NZS). Later, as the Lodz University students were joined by those from the Lodz Technical University and Medical School, and then by students in Poznan, Krakow and Warsaw, their package of "postulates" grew to more than fifty issues.

The problem of getting NZS registered had been dragging on since last November, when a limited sit-in at Warsaw University won a promise that the ministry would produce the necessary regulations by 20 December. Difficulties with the statutes of NZS were finally resolved last week, by the inclusion of a clause stating that NZS would abide by the constitution of the Polish People's Republic, but without specific mention of the "leading role" of the Party.

The major part of the Lodz Accord, however, sums up progress on the promised liberalization of Polish academic life. Several clauses therefore simply reiterate what has already been conceded. These include: the abolition of "reserved" places at universities, granted at the discretion of rectors or ministry officials to candidates whose performance in the entrance examinations did not merit their admission; university courses to be decided by the staff of the universities concerned; staff appointed on academic merits only; student participation in university government, and the election of university rectors by the academic senate in secret ballot.

Of the new demands raised at Lodz, the most radical have been dropped, including the reduction of military service and the abolition of compulsory courses on Marxism. (Some choice in "sociopolitical subjects" has, however, been conceded.) One major gain for the students concerned language courses. This had been strongly opposed by the minister, Dr Janusz Gorski, who had argued that a university is not geared to teaching foreign languages *ab initio*. Nevertheless, there will now be a wider choice of languages to be studied as subsidiary subject, in effect ending the compulsory Russian which many science students in particular resented. Having had several years of Russian at school, they say they would like to study a Western language, to have greater access to current research literature.

Access to information should also be facilitated by clauses promising larger editions of textbooks (most students now have to make do with secondhand texts), more foreign currency for buying foreign journals and research apparatus and more open availability of existing literature.

A new system of student grants "more in tune with the principles of social justice" is promised for 15 May, when it will be submitted to the students for consultation. By May, too, the detested "practical training" in manual labour will be replaced by paid voluntary physical work.

Student participation in university senates and faculty councils is set at 20–33 per cent, the student delegates to have full voting rights except in the awarding of academic degrees and titles.

The students also seem to have won their demand that the police should not be able to enter university premises at will. This clause, however, will presumably have to undergo some modification before the new legislation on higher education finally comes before the Sejm (Parliament), if campuses are not to provide an unintended sanctuary for, say, a purse-snatcher on the run. Inclusion of the clause, however, seems to reflect just how far the authorities are prepared to accept the concept of university autonomy.

What is clearly less acceptable, however, is the prospect of further unrest. Before finally approving the NZS statutes, therefore, Dr Gorski made sure that they contained some limitation on future militancy. The ministry's revisions laid down that strike procedures would follow the pattern of the "Solidarity" statutes, with the additional proviso that a sit-in can be proclaimed only by the majority decision of a specially convened meeting of a students' organization, in consultation with the authorities of the higher educational establishment(s) concerned.

Vera Rich

US science budget

Reagan's way

Washington

In the absence of any explicit science policy — and, indeed, of any official presidential science adviser — the new Reagan Administration has adopted a "back-to-basics" approach in deciding where the budget axe should fall on federally sponsored research programmes.

Last week, Mr Reagan submitted to Congress the cuts which he is proposing, as part of a "national program for economic recovery", in the budget recommendations made by Mr Carter last month.

As expected, the main cuts will fall on those additional areas of responsibility which the federal government has taken on in recent years but which Mr Reagan is suggesting should be returned to individuals, to states or to private corporations and other institutions.

In the universities, for example, he proposes to eliminate a new fund for modernizing research equipment which Mr Carter had proposed creating in the National Science Foundation, with an initial budget of $75 million. Mr Reagan also wants to cut federal support for biomedical research institutions previously provided through the National Research Service Awards.

The Department of Commerce's National Oceanic and Atmospheric Administration (NOAA) would see its budget cut by more than two-thirds,

0028-0836/81/090737-02$01.00

Threat to solar mission

Washington

European scientists could suffer directly from Mr Reagan's proposed budget cuts through a recommendation that the United States reduce its commitment to the international solar polar mission, a two-spacecraft programme run jointly by the National Aeronautics and Space Administration (NASA) and the European Space Agency (ESA).

Although no details of the reduced commitment have been officially announced, the White House is said to have suggested that NASA should stop work on its own spacecraft. This would effectively eliminate half of the project, and seriously reduce its scientific value, much of which depends on the simultaneous collection of data from the two spacecraft as they follow polar orbits around the Sun.

NASA and ESA officials are now discussing the implications of Mr Reagan's proposal, which could still be modified before the details of the new budget are announced on 10 March. The solar polar mission was threatened with termination by Congress last summer, but survived after vigorous intervention by the State Department and the Office of Science and Technology Policy.

Under the budget proposal submitted to Congress by President Carter last month, the two spacecraft would be launched from the space shuttle, using a modified Centaur launcher as a substitute for the delayed inertial upper stage, early in 1986. **David Dickson**

---

including an end to grants to states to protect their coastal zones, a 50 per cent reduction in support of college research under the Sea Grants programme, and the deferment of the National Ocean Satellite System (NOSS).

As for the private sector, a firm belief that the federal government should not interfere with the mechanics of the marketplace is reflected in substantial cuts to the Department of Energy's research and development budget. These would eliminate many of the department's efforts to demonstrate the commercial potential of new energy technologies, such as synthetic fuels, coal liquefaction and solar energy; but the aim is to maintain a basic commitment to long-range research projects considered too expensive or too risky by the private sector.

Public reaction to the proposed cuts from the scientific community has so far been muted. This is partly because precise details of where the cuts will fall will not be announced until 10 March and partly because there is little at present to be gained in Washington by speaking out against massive cuts in federal expenditure. Privately, however, laboratory chiefs and university presidents are already pulling all the strings they can, both within Washington's scientific establishment and among their congressional allies, to protect their own research programmes.

Some may already have been effective. A proposal from Mr David Stockman, director of the Office of Management and Budget, to eliminate the National Aeronautics and Space Administration's Galileo mission to Jupiter was removed from the President's message to Congress. Given a decision to defer the Venus Orbiting Imaging Radar, this would have virtually wiped out all future planetary research at NASA's Jet Propulsion Laboratory in California, Mr Reagan's home state.

On other proposals, there are bitter fights in prospect. Most of the projects that Mr Reagan is proposing to defer have been argued for by the scientific community strong and hard. These include NASA's gamma-ray observatory (already approved for funding by Congress), the National Science Foundation's 25-metre millimetre-wave radioastronomy dish and the NOSS satellite system.

Funding for space transportation systems will be maintained at a level adequate to cover the costs of the space shuttle, at the expense of slower development for Spacelab, and the rescheduling of space science flights — Galileo, for example, is likely to be shifted back from a 1985 to a 1986 launch. There will also be no funds for the solar electric propulsion system for which, in the absence of a Halley's comet mission, no applications have been approved.

At the National Science Foundation, budget restrictions will, as previously rumoured, be concentrated on programmes that are "narrowly focused or of less immediate priority" — such as innovation in small businesses and international scientific efforts — as well as on new initiatives in science and engineering education, and on research in the behavioural, social and economic sciences.

In contrast, there would be no reduction in the previously proposed 17 per cent increases for research in the mathematical and physical sciences, or the 20 per cent increase for engineering research. Both are considered by the new Administration to be "of relatively high importance to future technological advancement and to the long-term health of the nation".

In energy research, Mr Reagan is proposing a reduction of $40 million in the $607 million which had been suggested for basic energy sciences. Details of how this cut will be distributed are still being discussed. Most of it is likely to fall on high-energy physics, which accounts for two-thirds of the total, and will suffer the delayed construction of new facilities.

Biomedical research has been left relatively untouched ; where the previous Administration had suggested a relatively modest 9 per cent increase for the National Institutes of Health (NIH), Mr Reagan is suggesting a slight reduction in both 1981 and 1982 funding that will reduce this to 6 per cent. Much of the saving would come from reduced payment to educational institutions for NIH research training, which the Administration says would eliminate the practice of paying more to an institution for a federally supported trainee than would be charged for those who are not federally supported.

The Administration says that even though its proposed new budget for NIH would not fully cover the projected inflation rate — and that real reductions below the present base will therefore have to be made across all NIH institutes — it is committed to maintaining a substantial number of new research awards. It is therefore likely to continue the previous Administration's strategy of focusing on competitive project grants, rather than programme grants or intramural research.

David Dickson

UK nuclear energy

CEGB sheepish

The British nuclear industry is outwardly unruffled by criticisms from the House of Commons Select Committee on Energy last week (*Nature* 19 February, p.621). The general response is that the committee has misunderstood many of the issues. The strongest reaction is to the committee's criticism of the government's 1979 statement on nuclear power, which the committee took to be a commitment to build one nuclear station a year for the coming decade. This, it is said, was never the intention, so that the committee's recommendation that each reactor should be judged on its merits is already part of public policy.

The Central Electricity Generating Board (CEGB), the organization most sharply criticized, was the most sheepish last week. There is plainly some foundation for the charge that it had not been forthcoming with up-to-date estimates of cost and electricity demand. On the complaint that nuclear power stations are 34 per cent more expensive to build in Britain than elsewhere, Mr Glynn England, chairman of the board, is to meet nuclear suppliers and subcontractors to find ways of cutting costs and improving productivity on nuclear plant sites.

Mr England does not, however, accept the committee's view that the ordering of a second pressurized water station should be delayed for six or more years until the first, now being designed for the Sizewell site, is operating. Detailed studies and a public inquiry should provide enough information for the board to decide whether subsequent reactors should be based on pressurized water (as at Sizewell) or gas-cooled technology.

The Nuclear Installations Inspectorate also says that the committee has misunderstood its role. In particular, it

0028-0836/81/090738-02$01.00

says there would not be enough work for a full-time ultrasonics expert, recommended by the committee for testing pressure vessels, and that this and other work will be contracted out when it lacks the appropriate experts on its own staff.

The inspectorate is nevertheless still short of nuclear inspectors. Thirteen posts out of a total of 102 remain to be filled and salaries are a problem. Although nuclear inspectors' pay is as good as or better than that of other inspectors, it is below that in the industries from which it has to recruit. The problem — that the inspectors' salaries are linked to civil service pay — cannot be solved by removing the inspectorate from the Health and Safety Executive, which the inspectorate says would complicate licensing procedures.

The committee is said also to have misunderstood the role of the chief scientist at the Department of Energy and of the UK Atomic Energy Authority in advising the government on nuclear matters. The Department of Energy says that its chief scientist is responsible for nuclear advice but that there were exceptions when Dr Walter Marshall held the post as well as that of deputy chairman of the UK Atomic Energy Authority. Dr Marshall's version of this difficulty is different. He said last week that during his spell as chief scientist at the department, he felt no conflict of interest but, with the minister's agreement, meticulously kept the chairman of the authority informed of the advice he gave on nuclear matters.

The response so far to the report has been laconic and avoids detail. A more considered reply is likely to be published by the Department of Energy some months from now. Another contribution is likely to come from the Monopolies and Mergers Commission when it makes its views known on the structure of the electricity supply industry on 2 March.

Judy Redfearn

UK science research

On the move

The Science Research Council's attempt to foster mobility among British academics has made a modest beginning. The first four awards under the council's Special Replacement Scheme were announced last week. The scheme is designed to release senior academics from routine duties for five years, replacing them with younger people, usually postdoctoral researchers. The four awards will be followed by a further eleven before July, after which the council hopes to make ten awards a year.

The first four awards go to people who will be released from some or all of their administrative and teaching commitments for up to five years, enabling them to concentrate on their research interests. Each of the four departments is advertising a vacancy for a lecturer, whose appointment will be financed wholly by the Science Research Council for the first five years of his tenure. In every other respect, however, those appointed will be fully-fledged members of the academic staff.

Here the similarity ends. Some of the senior academics will return to their original position after five years. During that time, the department, which has guaranteed tenure to the new appointee, will have either found money elsewhere or lost a member of staff (by foul means or, more probably, fair). In other cases, the senior person will himself be retiring.

The Science Research Council, which has designed the scheme for flexibility, makes no stipulation about the areas of research involved, although it does intend to be represented on the selection boards for new appointees. In the cases so far announced, one professor should gain a member of staff in his own field of research, while another's department is to advertise for applicants for any of its research areas. Much discussion takes place behind the scenes between the council and the university concerned, and Sir Harry Pitt (ex-vice-chancellor of the University of Reading) is go-between and honest broker for the scheme.

The Science Research Council, through its boards and subcommittees which allocate grants among the applicants (30 of whom are now being considered), hopes to ease stagnation in research areas that it feels deserve encouragement. Awards have been given to Professors D. H. Everett (physical chemistry, Bristol), J. G. Powles (physics, Kent), M. Symons (chemistry, Leicester) and R. Butterfield (civil engineering, Southampton).

Philip Campbell

Authority more critical

The United Kingdom Atomic Energy Authority made a forceful response last week to the critical report of the House of Commons Select Committee on Energy (see *Nature* 19 February, p.621) Dr Walter Marshall, the bulky and voluble Welshman who succeeded Sir John Hill as chairman at the weekend, was quickly in action with his account of where the select committee had gone wrong.

The committee's wrath was directed chiefly at the Central Electricity Generating Board, but it also asked that the authority's role in the development of nuclear power in Britain should be restricted to research on long-term projects (fast reactors and fusion devices) and others where interested parties chose to commission work.

No-doubt Marshall

Marshall argues that this conclusion is mistaken. Thus he justifies the authority's work on the safety of pressurized water reactors (now costing £10 million a year) on the grounds that the authority is more independent than the would-be builders of the plant, the generating board, and less likely to continue indefinitely in the field than, say, the Nuclear Installations Inspectorate.

On the select committee's opinion that the authority should not be the public shareholder in the National Nuclear Corporation, the publicly supported construction consortium, Marshall says that the only effect of such a change would be to replace him by a civil servant as a director of the corporation. At present, he says, the authority's representation is the only source of independent criticism on the board.

The recommendation that the authority should quickly make an assessment of the Canadian CANDU heavy-water reactor system is similarly unwelcome. Marshall says that the committee has underestimated the difficulty of adapting even well-established reactor systems to British safety regulations, and estimates that a proper assessment would require two years of hard work. He points out that the select committee overlooked the authority's role in the development and management of the nuclear fuel cycle.

Dr Marshall's succession as chairman of the authority — he has been waiting in the wings for several years — presages a change of style. He is both outspoken and ebullient. He has his roots in the research establishment at Harwell (where he will keep an office). Last week he was saying that there will be no cause for changing the role of the authority until fast reactors are commercial realities some time in the next century. But he plans that the authority should become more skilled at explaining what it is about.

Community research

Project sharing?

Brussels

The European Parliament has now called for more community research. This arose at a meeting between the Parliament's Science and Energy Committee, the Dutch Minister for Science and Technology, Anton van Trier, and Dr Guenter Schuster, the director general for research, science and education of the European commission.

0028-0836/81/090739-02$01.00

Mr van Trier pointed out that between 1970 and 1980, Community expenditure on research and development had increased by 18 per cent, but that out of the 20,000 million European Units of Account (EUA) (1 EUA = £0.56) which the member states spent on their energy and research programmes in 1980, only 1.5 per cent was spent jointly. The president of the committee, Hanna Walz, while endorsing Mr Van Trier's affirmation of the significance of Community research, pointed out that there is a considerable gap between the declared intentions of the Council of Ministers and its actions.

Other members of the committee thought that the time was ripe to set in motion a "real Community research policy", since major areas could not be adequately tackled by each country on its own. Dr Schuster said that Community research would continue to concentrate on specific areas, particularly nuclear power, energy and environment, and pointed out that the Community contribution in these areas is 30 per cent, 10 per cent and 20 per cent respectively of total Community spending.

Mr van Trier and the committee agreed that a European market should be created for micro-electronic components and products, but that coordinating national programmes would only be feasible for large projects. The companies themselves must establish relations in order to coordinate the proposed research programmes. **Jasper Becker**

US Cabinet appointments

Conservatives in

Washington

One of the few bright spots for US environmentalists in the Cabinet appointments has been Mr Reagan's nomination of Mr James Buckley, a member of the US Senate from 1971 to 1977, as Under-Secretary of State for National Security, Science and Technology. If confirmed by the Senate, Mr Buckley will be directly responsible for the State Department's Bureau of Oceans and International Environmental and Scientific Affairs. Under a reorganization plan being discussed in the White House, the bureau may also be given responsibility for nuclear non-proliferation policy.

Mr Buckley is a conservative Republican. He voted against the War Powers Act giving Congress greater control over presidential decisions, and also opposed the first Strategic Arms Limitation Treaty (SALT), because it limited the United States to the construction of only two anti-ballistic missile sites — which were never built.

As a member of the Senate's environmental pollution subcommittee and its environmental science and technology subcommittee, Mr Buckley helped to forge much of the stringent environmental legislation of the 1970s. He clearly intends to take a close personal interest in environmental issues in his new post. High on his agenda is discussion with Canada of the effects of acid rain from the north-east states. Another issue is international attempts to prevent the extinction of endangered species; Mr Buckley told his nomination hearing in the Senate last week that "as a friend of the snail darter [whose potential extinction was used to hold up a federal dam project] I look forward to extending my responsibilities".

One potential dispute has already been headed off by the State Department. In its preliminary proposals for budget cuts, the Office of Management and Budget had suggested eliminating the $10 million contributed by the United States to the United Nations Environment Programme (UNEP). This — almost a third of the agency's budget — would have devastated UNEP's future programmes, but was successfully resisted by Mr Haig, and a contribution of $7.2 million is being proposed. In his Senate hearing, Mr Buckley said this would be "foolhardy".

Nuclear non-proliferation policy will be more difficult to deal with but will be high on the new Administration's agenda, since India is already preparing to make a further application for the export of enriched uranium to its Tarapur nuclear plant. Mr Buckley told the Senate Foreign Relations Committee that the Reagan Administration was completely reviewing non-proliferation strategy.

Mr Buckley, who ran for the Senate in Connecticut, had been tipped as the new administrator of the Environmental Protection Agency. In fact, the White House announced last week the nomination of a Colorado attorney, Mrs Anne Gorsuch, a close political ally of Interior Secretary James Watt, to head the agency. Both nominations have generated protests from environmentalists.

David Dickson

UK medical research

Money to spend

A £350,000 windfall has landed in the hands of the British Medical Research Council's Laboratory of Molecular Laboratory, Cambridge. The money was donated quite unexpectedly by Mr Thomas Usher, chairman of the Canadian company, Dextran. Since Mr Usher first approached the laboratory last May, a fund has been set up to support research fellows and students over the next seven years.

The offer of money comes with no strings attached, and the company had previously had only brief contact with the laboratory — many years ago Dr Max Perutz gave Mr Usher some advice.

The staff of the laboratory has agreed with Mr Usher that the money should be used to support research staff, the most serious hole left by cuts in the Medical Research Council's budget. The resulting fund will provide £50,000 a year for one to three-year fellowships, short fellowships for visiting scientists and studentships over the next seven years.

The scheme is to get under way in earnest next October. The trustees of the fund — Drs Sydney Brenner, director of the laboratory, Frederick Sanger, John Gurdon, Hugh Huxley and Aaron Klug — will decide on the next recipients in June.

Judy Redfearn

High-energy physics

China backs off

Washington

Economic problems have forced the People's Republic of China to postpone construction of a 50 GeV particle accelerator scheduled to be built near the Ming Tombs, north-west of Peking.

The accelerator, to have been built with the assistance of the US Department of Energy, was central to the agreement between China and the United States signed by President Carter and Vice-Premier Deng Xiao Ping in Washington two years ago.

US official who visited China last month were told that although construction was being deferred as part of a major cutback in capital construction projects, the delay did not imply a reduced commitment to research and training in advanced science and technology. The officials feel, however, that a "softening" in China's previous commitment to high-energy physics is inevitable.

Under the agreement, the Department of Energy would have carried out much of the construction of the components of the accelerator, receiving purchase orders over a period of five years of between $100 and $200 million for work that would have been carried out at the national energy laboratories. Subsequently the terms were changed so that the Chinese would carry out most of the design and construction work, and the United States would only provide basic training and advice.

The Chinese have also told the National Aeronautics and Space Administration that they will have to postpone the planned purchase of a new US-built telecommunications satellite system, another major component of the science and technology agreement. Four major contractors had already discussed with the Chinese the specifications of such a system, and were preparing bids. In a letter, the head of the Chinese academy of space technology, Dr Ran Xin-Mon, has now said that China was being forced to reconsider the whole of its space programme in the light of its economic situation.

China is, however, continuing negotiations over the purchase of equipment to receive geophysical information from the LANDSAT remote sensing satellite. It has

0028-0836/81/090740-02$01.00

also said that it intends to reschedule the satellite deal when funds are available.

According to Representative Donald Fugua, chairman of the House of Representatives Science and Technology Committee, who headed the delegation to Peking, China has decided that it will have to cut out about half of its ambitious construction plans in science and technology — including plans for a new steel mill to have been built outside Shanghai. But Chinese officials have stressed that other activities, such as scientific exchanges and research programmes will not be affected.

David Dickson

Soviet space research

Signs of strain

The planned Franco–Soviet mission to Halley's comet in 1986 turns out to involve a substantial cutback for the planned joint mission to Venus in 1984. This development, first indicated last summer, was finally confirmed two weeks ago in Paris. Two of the original four Venus probes have now been assigned to Halley, so that the French have had to abandon plans for a large balloon which would have analysed the atmosphere of Venus. Although the reduced Venus mission could still have accommodated a smaller balloon, the consequent problems of high-temperature electronics could not be solved in time.

According to M. Hubert Curien, president of the Centre National d'Etudes Spatiales, the French side has few regrets. The new programme, he said, is "very full and very attractive". Nevertheless, the final announcement of the scaled-down Venus mission was a reminder that the resources of the Soviet space programme, though vast, are not infinite. It came only a few days after *Pravda* had published two long articles of no great topicality clearly intended to present the Soviet space effort in a favourable light.

One dealt with the detection of iron in the lunar regolith samples recorded by the Luna-16 probe in 1970 and one with the seventieth anniversary of the birth of the late Mstyslav Keldysh, whom Khruschev brought out of the field of military rocketry to lead the academic space programme.

The question of the scale of Soviet space research will arise this week, when the twenty-sixth congress of the Communist party of the Soviet Union will be required to approve the basic guidelines for the next Five-Year Plan. As with the two previous plans, these will include a commitment to space exploration "in the interests of the national economy". This is an empty formula for deep-space research, although satellite photography is playing an increasing part in a number of aspects of Soviet planning, from fish-spotting to geological surveying. The costs of the programme are, however, never published.

Hints that Soviet space spending may be subject to increasing financial constraints have, however, been dropped in recent months. There seem to be no further plans for Comecon participation in manned flights after Mongolia and Romania have put a cosmonaut in orbit. Soviet planners have so far failed to respond to Bulgarian hints that, as their cosmonaut, Georgi Ivanov, failed to complete his mission (his Soyuz transport craft could not link up with the Salyut station), Bulgaria should be allowed another turn, especially in its 1,300th year of statehood. Instead, Bulgaria has been promised two unmanned probes instead of the original one.

The Soviet commitment to Comecon participation in space research nevertheless continues. A new scientific cooperation programme with Poland, announced last month, put special emphasis on space research. Poland, the homeland of Copernicus, may have a special place in Soviet space planning but the Soviet Union's contribution to Comecon collaboration is substantial. It pays the total cost of the launching and ground control. The participating Comecon partner simply has to pay for its own apparatus and the associated data processing — a privilege also extended to the French.

Vera Rich

Science and government

Lords look now

The House of Lords Select Committee on Science and Technology has taken the unusual step of making a public appeal for opinions on the subject of its latest inquiry — science and government. The inquiry's chairman will be Lord Sherfield. Lord Todd, who is thought to have instigated the inquiry, and who was expected to take the chair, seems to have stepped down in the belief that his strong views can be better aired from the body of the committee.

Central to the inquiry will be the need for a chief scientific adviser to the government and the success of the Rothschild customer-contractor principle. The chief scientific adviser's post was abandoned in 1974 after the Rothschild report recommended that individual government departments should take more responsibility for seeking advice and commissioning research. The system of departmental chief scientists that resulted was intended to enable government departments (the "customers") to commission research within the research councils (the "contractors") with money transferred to them from research council budgets.

Although the principle has worked well in some departments, it has been disastrous in others. The Department of Health and Social Security has acknowledged that it cannot place contracts for biomedical research, while the Ministry of Agriculture, Fisheries and Food is considering a proposal to abolish the post of departmental chief scientist as part of its changing relationship with the Agricultural Research Council (*Nature* 1/8 January, p.2).

The committee started taking oral evidence yesterday (25 February) from Sir Ian Bancroft, head of the home civil service. Next on the list are Lord Trend, former Secretary to the Cabinet and author of the 1964 report on the organization of civil science, and Sir Hermann Bondi, chairman of the Natural Environment Research Council and a former chief scientist at the Ministry of Defence and Department of Energy. Those wishing to submit evidence should write to the Clerk of the Select Committee on Science and Technology, Committee Office, House of Lords, London SW1 by 31 March 1981.

Judy Redfearn

Questions to answer

A *Machinery of government*

(1) Should scientific advice and/or research procurement be a distinct function of government separate from the existing departmental structure?

(2) How successful is the system of departmental chief scientists in procuring advice, managing research and influencing policy?

(3) How well supported are ministers when judging scientific priorities in decision making, particularly if government departments are not in agreement?

(4) How far is the scientific advice sought by government geared to supporting predetermined objectives?

B *Finance*

(1) How satisfactory is the division of financial responsibility between the research councils (as a group) and government departments funding research on the customer-contractor principle?

(2) Is any research which could be of real value to government being neglected for lack of identified customers or because it is peripheral to the interest of several customers; if so, what changes could rectify this?

(3) Are any changes in research budgets desirable?

C *Machinery of science*

(1) How adequate are the channels of communication from the scientific community to government, and vice versa?

(2) Is there satisfactory contact between those administering science in higher education, industry, the research councils and government?

(3) How could statutory procedures for consultation by government in scientific matters be improved?

(4) Are existing sources of advice adequate to ensure that the United Kingdom gains all it can from EEC and international research programmes?

D *Scientific manpower*

What manpower constraints are there on the provision of scientific advice to government?

0028-0836/81/090741-01$01.00

CORRESPONDENCE

Genes and race

Sir — I write in reply to Dr Steven Rose's letter (*Nature* 22 January, p.335), which drew attention to the fact that a right-wing journal, *New Nation*, has quoted me, together with other evolutionary biologists, in support of their view that our genetic constitution makes it impossible for us to live in a racially integrated society. I welcome the opportunity to say that there is nothing in modern evolutionary biology which leads to this conclusion.

John Maynard Smith

University of Sussex,
Falmer, UK

Museum debate

Sir — I have been following the "great museum debate" in your pages with a profound sense of detached amusement. But as matters are quickly reaching a level of absurdity that may inspire me to write the 15th Gilbert and Sullivan opera, and as I am, in a sense, the focal point for Halstead's glorious uproarious misunderstanding, I suppose I should have my say.

Halstead began all this by charging that the venerable Natural History Museum is now purveying Marxist ideology by presenting cladism in its exhibition halls. The charge is based on two contentions: (1) a supposed link between the theory of punctuated equilibrium, proposed by Niles Eldredge and myself, and cladistic philosophies of classification; and (2) an argument, simply silly beyond words, that punctuated equilibrium, because it advocates rapid changes in evolution, is a Marxist plot. For the first, there is no necessary link unless I am an inconsistent fool; for I, the co-author of punctuated equilibrium, am not a cladist (and Eldredge, by the way, is not a Marxist, whatever that label means, as if it mattered). Under cladism, branching events may proceed as slowly as the imperceptible phyletic transitions advocated by the old school. Punctuated equilibrium does accept branching as the primary mode of evolution, but it is, fundamentally, a theory about the characteristic rate of such branching — an issue which cladism does not address.

For Halstead's second charge, I did not develop the theory of punctuated equilibrium as part of a sinister plot to foment world revolution, but rather as an attempt to resolve the oldest empirical dilemma impeding an integration of palaeontology into modern evolutionary thought: the phenomena of stasis within successful fossil species, and abrupt replacement by descendants. I did briefly discuss the congeniality of punctuational change and Marxist thought (*Paleobiology*, 1977, p.145) but only to illustrate that all science, as historians know so well and scientists hate to admit, is socially embedded. I couldn't very well charge that gradualists reflected the politics of their time and then claim that I had discovered unsullied truth. But surely Halstead, who has done some statistics in his day, knows that correlation is not cause. If I may make a serious point: I grew up frightened in a leftist household during the worst days of McCarthyism in America; and I know that what seems peripheral or cranky today can become a weapon tomorrow (consider the current creationist surge in America). May we avoid red-baiting; it may not always be harmless.

I saw the cladistic exhibits last December. I did not care for them. I found them one-sided and simplistic, but surely not evil or nefarious. I also felt, as a Victorian aficionado who pays homage to St Pancras on every visit to London, that most of the newer exhibits are working against, rather than with, the magnificent interior that houses them. But I would not envelop these complaints in ideological hyperbole; Halstead has said enough.

Stephen Jay Gould

Harvard University,
Cambridge, Massachusetts, USA

Last word?

Sir — It is a little late in the day for Stephen Gould to try and come the innocent. If he did not want "Halstead's glorious uproarious misunderstanding" to get under way, he should have avoided dragging Engels on to his side in the first place[1]. Mind you, even this might not have worked, for the "political" implications of punctuated equilibria have not gone unremarked, as some of the recent correspondence has made manifest.

I have taken Engels and Lenin as my main sources on dialectical materialism, which I have sought to apply in the conduct of my own researches. There is only one point, but this is fundamental, at which I would part company with Marxism and that is the nature of qualitative changes, which I see not as sudden leaps but as gradual in the tradition of Charles Darwin. I have recently been nonplussed to learn from Stephen Gould that "many orthodox Marxists have been quite content with Darwinian gradualism" (ref. 2). This is equivalent to someone, who insists that Christ was a myth, being considered an orthodox Christian. But perhaps in the United States, I would be deemed an orthodox Marxist!

When it comes to the cladists with their punctuated tendencies, we run into a perfectly ludicrous source of semantic confusion. If, as some of the correspondents have insisted, cladistics is concerned only with pattern and not process, then obviously there is no point in arguing further, because I am concerned primarily with process. I wrote about the kind of classical Hennigian cladistics actually being presented in the public galleries of the British Museum (Natural History) and clearly explained in their accompanying booklets, and not the new transformed variety of Patterson[3] and others.

Tempting though it may be, I am sufficiently modest to decline the mantle of oracle proffered by Rosen[4] with regard to the origin of *Homo sapiens* from *Homo erectus*. I claim no special insight in these matters but merely reported the considered and published consensus of the staff of the British Museum's own Sub-Department of Anthropology. Wood[5] has drawn attention to the "dubious academic practice" of ignoring "uncomfortable" evidence — the scandal of this is that it was deliberate, involving, as it did, the overruling of the museum's own experts. Critical scientific evidence is being deliberately withheld from the public who are, in consequence, being seriously misled as to the nature of "Man's place in evolution". All is apparently being subjugated to a chosen dogma. I have been roundly abused for implying that a far left political connection might be involved, but the present dogmatic policies seem to bear its unmistakable stamp.

The British Museum (Natural History), London, is a major public scientific institution in this country and as such should be accountable to the public. It is surely reasonable to expect the Director to answer the charges that have been levelled — a continued "dignified silence" in the present circumstances is simply not good enough.

Badger controversy

Sir — On 11 December 1980 the Mammal Society published a letter in *Nature* drawing attention to some of the many anomalies in the Zuckerman report. The reasons we started an open discussion of the report are obvious. Badger gassing started in 1975; nearly six years later, after the expenditure of a great deal of time, money and effort, it is our belief that there is no unequivocal evidence that the present gassing policy is likely to produce a long-term solution to the problem. We suggested that the Zuckerman report is one-sided in its interpretation of the evidence, and that the conclusions and recommendations in the report are too categorical and do not take sufficient account of the complexity of the problem.

Following our original letter, three letters have been published in *Nature*. Dr Plowright (1/8 January 1981, p.8) presented no new information, nor did he answer any of the points we raised, and so his letter will not be discussed further. Dr Yates (22 January 1981, p.218) questioned a graph sent to Lord Zuckerman for his comments. This graph was simply intended to show that the rate of decline of TB was similar in the South West to that elsewhere in England. That the incidence of TB was different in the two areas was never disputed. Dr Yates published an alternative graph, which was simply another presentation of the same data; it showed that the incidence of TB varies in different parts of the South West. That is the very point we stressed in our original letter. Dr Yates' graph also showed that there was a decline in TB in all the regions sampled, irrespective of whether badger gassing was carried out in that area. That is the only point our original graph was designed to demonstrate.

In fact Dr Yates' graph has highlighted the

Models of speciation — the evidence from *Drosophila*

Library
College
Upper Circular Road
CALCUTTA

from J.S. Jones

If Lewontin's (1974)[1] claim that "we know almost nothing of the genetic changes that occur in species formation" is still true then we must by now know it in remarkable detail, for the literature of evolutionary biology has been filled with speculations, observations and experiments on this very subject for the last five years. There are two models of the origin of species. In one of these[2] the division of a population into two genetically incompatible entities is seen as a by-product of the gradual adaptation of its geographically isolated parts to different selection pressures. Hybrids between the evolving populations are relatively unfit because they have accumulated different alleles with individually minor effects. Reproductive isolation thus arises at first from the incompatibility of separately developing gene pools; should these pools later come into contact, selection may lead to the evolution of behavioural or ecological barriers which reduce the frequency of hybrid matings. The origin of a new species is the result, writ large, of the familiar process of natural selection within an existing species.

A second model — that speciation is brought about by a 'genetic revolution' — has recently returned to prominence[3-5]. This theory places less weight on selection, and emphasizes the importance of random processes in the origin of taxonomic groups. A small and isolated population of an originally widespread and highly variable species will, it is suggested, undergo major genetic changes because of the chance loss of alleles in the small founding sample, the increased frequency of homozygotes caused by inbreeding in the early generations and the resulting disruption of interacting complexes of genes and of developmental processes under genetic control. The new isolate may move into previously unexploited ecological niches and undergo an enormous increase in numbers (the 'population flush'[3]) with a consequent relaxation of selection against deviant individuals which will further favour the success of the genetic revolution. Rapid fluctuations in population size and random gene frequency changes in these early generations will quickly lead to the evolution of reproductive incompatibility with the parental population. According to this view, isolation causes speciation, rather than sometimes allowing it to take place as an incidental result of slow adaptive evolution.

Recently, some palaeontologists have claimed that this model of speciation can explain the apparent gaps in the fossil record[6]. Rather than accepting that the gaps reflect the record's incompleteness, they claim that they are the result of a pattern of bursts of rapid speciation interspersed with long periods of evolutionary stability. Only rarely will members of the small speciating population be fossilized, so that the lineage will show what are known as 'punctuated equilibria' — a long series of unaltered fossil forms followed by a rapid shift to a new type. Species are therefore discrete units not only in space, but also in time.

Some biologists have interpreted this view of evolution as an attack on the fundamentals of Darwinism and a bitter dispute is still taking place. However, the problem can be approached experimentally using *Drosophila*. There is now good evidence that some populations may indeed contain hidden genetic variation sufficient to cause 'instant speciation' and that rapid fluctuations in population size can sometimes produce reorganizations sufficient to lead to reproductive isolation within a very few generations.

Drosophila mercatorum is normally sexual, but in the laboratory a female can produce parthenogenetic clones. It is possible to freeze the recombinant offspring of a single heterozygous female into a number of diverse clones, and by comparing these to estimate the amount of hidden genetic variation in the original population. Templeton and his colleagues[7,8] find that such clones differ from each other in morphology, in behaviour and in aspects of fitness sufficient to cause rapid changes in their frequency when competing in a population cage. Most important, when females from some of the derived clones are tested for mating potential with males from their ancestral sexual population, they show strong reproductive isolation from them. What is effectively a new species of *Drosophila* has therefore arisen as a result of reorganizations of the genome of a population within a few generations.

Sexual populations may also undergo genomic transformations of this kind. A population of *D. pseudoobscura* was placed in a large cage and allowed to expand rapidly in numbers[9]. At the peak of the population flush, 8 single pairs were chosen to start 8 new populations, each of which grew to a large size. These populations were put through three further cycles of reduction and expansion. Interpopulation tests of mating preference showed that in a third of the derived cages there was a significant tendency for individuals to prefer to mate with others from their own population. Reproductive isolation was the result of the demographic (and associated genetic) changes within the populations, as control populations isolated from each other without undergoing rapid changes in population size did not mate preferentially.

Population flushes in nature are most likely to occur in organisms which disperse easily, have short generation times and live in regions where new and unexploited habitats become available. The *Drosophila* of Hawaii are a good example of such a group. The Hawaiian archipelago came into being some 40 million years ago, and the youngest island is about 700,000 years old. Nearly a third of all known *Drosophila* species occur only in Hawaii, suggesting that speciation has been extremely rapid. Carson[10] suggests that this reflects a history of founder events, population flushes, and the formation of new gene combinations as flies blew from one island to that formed next in the volcanic chain. On the basis of chromosome phylogeny he estimates that as few as 22 inter-island colonizations (many of which may have involved just one fertilized female) over only 6 million years will account for speciation in the best known group of Hawaiian *Drosophila*. The rapidity of speciation is a result of random events and demographic changes leading to reproductive isolation, rather than of slow adaptive evolution on each island.

The patterns of reproductive isolation between flies from different islands support this view[11]. In *Drosophila* the female selects the mate; a courting male must produce the correct sequence of behaviours before being accepted, but a male will attempt to mate with almost any available female. Reproductive isolation between species of Hawaiian *Drosophila* from different islands is often asymmetrical. A female from a new species on a young island will accept a male from the ancestral population, but a male of the new species cannot successfully court a female of the ancestral species. This is evidence for

0028-0836/81/090743-02$01.00

rapid speciation in a founding population; the males of the derived species lost, by chance, in their small founding population some of the behavioural repertoire which made them acceptable to ancestral females, but the ancestral males retain all the genes for the behaviour needed to stimulate females of both species.

This process has been simulated in the laboratory by an inadvertent experiment of the kind familiar to *Drosophila* geneticists[12]. A stock of Hawaiian *D. silvestris* underwent at least two population crashes (perhaps to a single fertilized female) during its stay in the laboratory. The derived stock showed strong behavioural isolation from freshly collected *D. silvestris* from the same location. Wild males successfully courted derived females, but derived males could not stimulate females from the ancestral population. Asymmetrical reproductive isolation did not develop as a by-product of slow adaptive evolution but resulted from extreme demographic changes.

As species are, by definition, genetically isolated from each other, it might seem impossible to investigate the genetics of reproductive isolation by carrying out breeding experiments. This apparent contradiction has been overcome in the Hawaiian *Drosophila*[13]. *D. silvestris* and *D. heteroneura* are known to be closely related, but differ markedly from each other in head shape. This is an effective behavioural isolating mechanism in the wild. It is possible to make fully fertile crosses between these species in the laboratory, and genetic analysis shows that the differences in head shape are due to a single sex-linked locus which influences the phenotypic expression of about 10 interacting autosomal loci. The genetic basis of each species' integrity thus depends on rather few loci — a result consistent with theories emphasizing the importance of random events in the origin of species.

Although these views of speciation as a 'revolutionary' process are now receiving much attention, there is also evidence strongly supporting the view that many species originate through the slow evolutionary accumulation of small variations. Recent theoretical work by Lande[14] shows just how effective selection acting on many genes with individually small effects can be in leading to the divergence of large populations. His predictions are supported by many experiments in which individual *Drosophila* prefer to mate with others from the same natural population[15] or in which the offspring of interpopulation crosses are less fit than those whose parents arise from the same population[16]. Laboratory stocks subjected to different temperature and humidity stresses accumulate over a period of time genetic differences great enough to lead to mating preferences or hybrid inviability[17]. Reproductive isolation has also been found to occur between populations of *Drosophila* and of house flies selected for high or low activity, for different bristle number and for DDT resistance[18-21].

In summary, there is convincing evidence for both models of the origin of species. In some lineages, speciation may result mainly from natural selection acting on genes with small effects, while in others it probably results from the disruption of a genetic system following the random colonization of a new environment by a small population. The two mechanisms are not mutually exclusive and within one genus both may be important. In *D. mercatorum* (where experiments with derived clones show that natural populations contain the genetic potential for very rapid speciation) geographically separated populations have differences in their behaviour which have arisen by the accumulation of many genes with small effects — and which are sufficient to cause considerable reproductive isolation[22]. In the Hawaiian *Drosophila*, also, where evidence for rapid speciation as a result of random effects is so strong, some populations from the same island have undergone considerable divergence which is not a result of founder events[23]. Any complete theory of the origin of species must recognize — as did Darwin himself — the importance of the joint action of random processes and of natural selection.

Models of speciation have recently become entangled with claims that the 'punctuated equilibrium' theory of evolution favoured by those responsible for the dinosaur gallery in the Natural History Museum reflects that of the evolution of society held by Karl Marx[24]. Whatever the scientific merit of an argument couched in terms of Dinosaurs versus Democracy, it is worth considering the attributes of a lineage liable to undergo rapid speciation by genetic revolution[4,5]. They include an abundant and freely interbreeding ancestral population, high individual mobility, and rapid reproduction. Although the *Drosophila* of oceanic islands fit these criteria well, it is hard to imagine any group less able to satisfy them than the dinosaurs. In particular, the idea of a windblown propagule of a pregnant female *Brontosaurus* is enough to strain the imagination of even a palaeontologist! ☐

MIGRATION OF THE WAGTAIL

I fear I may be attempting to trespass too frequently on the columns of *Nature* recently, but the paper on the subject of wagtails taking a passage on the backs of cranes in a long flight, resembles so much a somewhat similar story told and believed in by the Indians in several parts of North America, that I venture to send you an account of it.

All the Indians (Maskegon Crees) round the south-western part of Hudson's Bay, assert that a small bird of the Fringillidae tribe takes a passage northward in the spring on the back of the Canada goose (*A. Canadensis*), which reaches the shores of Hudson's Bay about the last week of April.

They say that they have often seen little birds fly away from geese when the latter have been shot or shot at.

An intelligent, truthful, and educated Indian named George Rivers, who was very frequently my shooting companion for some years, assured me that he had witnessed this, and I believe I once saw it occur.

It is only the Canada goose that these little migrants use as an aerial conveyance, and certainly they both arrive at the same date, which is a week or two earlier than the other kinds of geese (*A. hyperboreus* and *albifrons*) make their appearance. I knew the little bird well, but it is so long ago that I have forgotten the name.

The Indians on the shores of Athabasca and Great Slave Lakes, both great resorts of wild geese, tell a similar story. If a fabrication, I do not see why it should be invented about the Canada goose only, and not about other species which are equally numerous.

All the Coast Indians of Hudson's Bay devote a month or more every spring to wild fowl (chiefly geese) shooting. As soon as the geese begin to arrive, the Indian constructs a concealment of willows and grass, usually near a pool of open water, at the edge of which he sets up decoys. When geese are seen approaching (usually flying at a great height) the Indian imitates their call, and the geese on seeing the decoys circle round, gradually coming lower down until within shot, when they are fired at. It is from these high-flying geese that the small birds are seen to come.

If the geese are flying low it is a pretty sure indication that they have already rested on the ground somewhere near, after their long flight, when of course their tiny passengers would have alighted. JOHN RAE

Last supper of two Indian Triassic reptiles?

from Barry Cox

Life restorations of two specimens of *Malerisaurus*, showing quadrupedal and bipedal gaits.

DURING the winter of 1965–66, Indian palaeontologists found a pair of skeletons of the crocodile-like phytosaurian reptiles in the late Triassic rocks of the Maleri Formation in the Pranhita-Godavari Valley, Andhra Pradesh, central India. They were found so closely associated that they soon became known as 'the loving couple'. During the removal of the soft, clay-like matrix from their skeletons, it soon became clear that they had also eaten a similar last meal, for within the rib cage of each there appeared the skeleton of a smaller reptile.

These two skeletons have now been described by Chatterjee (*Phil. Trans. R. Soc.* **B291**, 163; 1980) as a new genus, *Malerisaurus*. It belongs to a group of still poorly known and poorly understood Permo-Triassic lizard-like reptiles that includes the ancestors of the lizards themselves. *Malerisaurus* was of considerable size, some 1.3m long, and it is notable for its rather large hind-limbs. The length of the fore-limb is only 59 per cent of the length of the hind-limb, and the latter is 74 per cent of the length of the trunk. Proportions of this kind are found today in a number of facultatively bipedal lizards, such as the frilled lizard *Chlamydosaurus*, and the life restorations of the two specimens that illustrate Chatterjee's paper show them in two alternative poses. The dentition of *Malerisaurus* suggests that it fed on the general range of invertebrates that is described as an 'insectivorous diet'.

The sedimentology of the Maleri deposits suggests that the environment of this part of India during the late Triassic was probably very similar to that found there today, with a subtropical monsoon climate. *Malerisaurus* therefore probably lived in a densely forested, lowland environment with lakes or flood-plains.

The Maleri fauna also contains a variety of other reptiles, as well as the large aquatic amphibian *Metoposaurus*. All of these belong to groups that are widely known throughout the Triassic world, and attest to the ease of dispersal through that ancient Pangaea world-continent.

Barry Cox is Professor of Zoology at Kings' College, London.

Is the Universe expanding?

from David A. Hanes

THE DISCOVERY by Edwin Hubble[1] that the Universe is not static, but an evolving entity, is surely the most important finding in extragalactic astronomy this century. Few astronomers would contest the view that the Universe is in a state of general smooth expansion. However, recent provocative statistical studies by J. F. Nicoll, D. Johnson, I. E. Segal and W. Segal[2] of the relationship between the redshifts of moderately nearby galaxies and their apparent brightnesses have brought this simple yet profound picture under attack.

In a general expansion, the recession velocity of a galaxy (or empirically its Doppler redshift) should be directly proportional to the distance of that galaxy. Nicoll *et al.* claim they can reject such a relationship; rather, their findings imply a quadratic relationship between redshift and distance for a moderately nearby sample of galaxies (those with recession velocities less than 5,000 km s^{-1}). Such a discovery is consistent with the predictions of I.E. Segal's[3] alternative world model, the chronometric cosmology, and at variance with the predictions of Einsteinian General Relativity. At the very least, these statistical demonstrations demand explanations in terms of unsuspected selection effects, subtly biased samples, or local anisotropies or inhomogeneities; and, should convincing explanations be lacking, they may suggest that the usual cosmological descriptions of the Universe are inadequate.

Edwin Hubble's original data suggested a linear relationship between velocity (inferred from redshifts) and distance (inferred from apparent luminosities) for galaxies. This relationship has an appealing simplicity, for in a universe in which we are in no preferred position and where there are no preferred directions — that is, in a universe where the 'cosmological principle' holds — it can be shown that such uniform expansion (or contraction) is the only permitted large-scale motion. The cosmological principle is justified both philosophically and empirically: the former in the neo-Copernican sense that we must assume that we are in no way singled out as special observers of the cosmos; and the latter in that galaxy counts and the isotropy of the cosmic background radiation suggest that the Universe is indeed homogeneous and isotropic on sufficiently large scales[4]. There are other reasons for the faith of astronomers in the expansion hypothesis: the expansion is associated with a characteristic time (which may naively be thought of as the time since the Universe was in a state of infinite density) which is closely comparable with the ages of the oldest known stars; and the discovery[5] of the predicted[6] cosmic microwave background strongly suggests that the Universe has evolved from a hotter dense state. Moreover, the Hubble expansion finds a natural theoretical framework — that of Einsteinian General Relativity — which in fact predates[7] the discovery of the expansion and which has been amply confirmed in the limited tests possible to date[8].

For all these reasons astronomers will be unmoved, except by unequivocal tests, to adopt alternative cosmological descriptions of the Universe. Segal's chronometric cosmology is one such description. It has been characterized[9] as a 'gravitational tired light' theory; that is, one in which observed redshifts for remote galaxies arise through the loss of energy by photons during their propagation rather than because of any systematic motions. In Segal's

David A. Hanes is at the Anglo-Australian Observatory in New South Wales, Australia.

0028-0836/81/090745-02$01.00

formulation, the chronometric theory reproduces many of the observational attributes of the cosmos, such as the universal background radiation; and the telling coincidence of inferred expansion age with stellar age is not a problem[10], although arbitrarily old galaxies may abound. Astronomers — indeed, all scientists — are reluctant to adopt purely *ad hoc* theories, those which follow rather than predict fundamental discoveries and which explain later observation by judicious manipulation of the theory, and this kind of criticism has been levelled at the now largely discredited Steady State cosmologies. However, Segal's chronometric cosmology does make a crucial prediction relating to the behaviour of the redshift–apparent magnitude relation for systems of moderate redshift (inferred velocities $\lesssim 5{,}000$ km s^{-1}): the observed relation should be quadratic.

The statistical study of such nearby systems is plagued by a variety of important selection effects. Complete redshift determinations are available only for the brightest few hundred galaxies. At fainter levels, galaxies of special interest — those in rich clusters, or those associated with bright galaxies — may provide additional data. The galaxy luminosity function is broad, and an apparently bright galaxy with well determined redshift may be a remote very luminous object, while nearby fainter galaxies go unstudied; thus volume-limited samples are not to be hoped for. Perhaps most important, the local dynamics enter into any analysis: the corrections for solar motion around our own galactic centre, the peculiar motions of single galaxies and the dispersion of velocities because of interactions in clusters of galaxies are all relatively large compared with Hubble expansion rate for the nearby systems: the motion of our own local group of galaxies, which appears to be falling into the rich Virgo cluster[11], may introduce systematic effects; and other anisotropies may be present.

Deviations from the simple Hubble law have in fact been noted in the past. Hubble[13] himself recognized a degree of nonlinearity in his data and concluded that the gravitational deceleration of the expansion was the cause. Vaucouleurs[13] interpreted similar findings in terms of local departures from the Hubble flow caused by the existence of a Local Supercluster of galaxies. Other anisotropic features in the flow, the so-called Rubin–Ford effect, have received various suggested explanations[14]. The lesson to be drawn is that the purely astronomical interpretation of such effects in not at all clearcut, even in the simplifying context of a general underlying expansion.

Statistical tests must obviate these problems by the careful definition of completely unbiased samples unaffected by subtle selection effects. The difficulty of the exercise is reflected in the fact that R. M. Soneira[15], in a careful statistical reworking of Segal's earlier analysis, found no disagreement with the expansion hypothesis but felt able to exclude the correctness of the chronometric prediction at better than the 99.999 per cent formal confidence level. However, Soneira's analysis has in turn been criticized by Segal[16] and by Nicoll and Segal[17], who reach the opposite conclusion at comparable confidence levels. Their latest papers represent the most exhaustive statistical analysis to date, with the authors concluding that. . . "the Hubble law lacks an objective statistical foundation".

The validity of this conclusion and the resolution of the questions raised about our understanding of the large-scale structure of the cosmos may come in further statistical analyses which confirm or deny the various treatments. It may be that considerably more observational data and careful mapping of local anisotropic effects will prove essential. If the suggested nonlinearities are found to exist, most astronomers will seek explanations in terms of local deviations from the Hubble flow rather than in the wholesale rejection of the presently believed cosmological description of the Universe, with its history of successful predictions and supportive tests. The onus is upon the advocates of alternative theories to demonstrate the absolute insufficiency of any such explanations. □

Parasitology in Venezuela

from Neil Brown and Win Gutteridge

THE study of parasitic diseases has for too long suffered from the geographical separation of pure and applied research efforts. Within the afflicted countries, research has concentrated on immediate clinical and epidemiological problems while more fundamental research has been confined to Europe and North America. As a consequence, both aspects of research have suffered, one through lack of modern know-how and the other through concentration on highly selective and convenient laboratory infections. A number of countries and international funding organizations have sought to end this separation and it is encouraging to report that, in Venezuela, a recent congress* demonstrated that fundamental research in parasitology is now being actively developed alongside clinical and epidemiological aspects.

Two protozoan diseases are of primary concern in Venezuela, Leishmaniasis and Chagas' disease. *Leishmania* are intracellular parasites of 'professional' phagocytes. Infection is initiated by a flagellated promastigote form inoculated by the sand-fly (*Phlebotomus*). Promastigotes actively secrete protein, and Hernandez and colleagues (Universidad Central de Venezuela, Caracas), in association with Greenblatt's group (Hadassah Medical School, Jerusalem), reported that as much as ten per cent of all protein synthesized is secreted. Although the secretory products have not been fully characterized, one, a glycoprotein with a high proportion of carbohydrate, has been shown by Hernandez' group to have the capacity to modify the membrane characteristics of macrophages.

Studies reported by Perez and associates (Instituto Venezolano de Investigaciones Cientificas, Caracas) have delineated a number of aspects of the host response to American cutaneous leishmaniasis. In syngeneic mice the type of lesion is determined mainly, but not exclusively, by the genetic composition of the host; parasite isolates also differ somewhat in their behaviour in one host genotype. Parasite destruction was shown by Perez to be mediated in an *in vivo* assay by peritoneal cells from immune animals and immune serum; non-adherent peritoneal cells were not protective. By contrast, in genetically susceptible BALB/c mice adherent cells were not protective and were found to have suppressor activity. Relating their laboratory studies to epidemiological observations, these workers were able to show that temporary protein deficiency ablates irreversibly the capacity of resistant C57BL/6 mice to resolve an active lesion. Other factors rather than simple killing of parasites by immune serum and activated macrophages must be involved in

---

*The 30th Convention of the Venezuelan Association for the Advancement of Science was held in Merida from 9 to 14 November 1980.

Neil Brown is in the Parasitology Division, National Institute for Medical Research, London and Win Gutteridge in the Biological Laboratory, University of Kent.

0028-0836/81/090746-02$01.00

Leishmania immunity, however, as even in C57BL/6 mice, lesions take 5–6 months to resolve, long after these immune responses appear. Practically nothing is known in detail about parasite antigenicity, particularly the antigenicity of the surface and secretory products of amastigotes, or the changes produced in the surface structure of the phagocytes they parasitize and eventually destroy. There is an urgent need to characterize the parasite side of the interaction and the role it plays in inducing parasite-specific and possible autoimmune protective and pathological reactions.

Little more is known of the biochemistry and molecular biology of *Leishmania* except in so far as it relates to energy metabolism, purine salvage and kinetoplast DNA. Ramirez and his colleagues (Universidad Central de Venezuela, Caracas) are now, however, beginning to probe the organization of the ribosomal RNA genes. They have estimated the molecular weight of the total genome to be 1.6×10^{11} (range for other protozoa 1–6×10^{11}) and that this includes about 350 copies of ribosomal DNA. An 8-megadalton fragment of total DNA, obtained by restriction endonuclease digestion with *Bam*HI and which hybridizes with ribosomal RNA, has been inserted into plasmid pBR322 and cloned in *Escherichia coli* x 1776. It should therefore be possible in future to study the ribosomal DNA of *Leishmania* in much more detail. In a complimentary investigation, Valbuena and his colleagues (Universidad Central de Venezuela, Caracas) have begun to study messenger RNA from the organism. They have developed a method for the isolation in high yield of polyribosomes which are active in a wheat germ-derived cell-free protein synthesizing system; messenger RNA is extracted from these.

Trypanosoma cruzi, the causative agent of Chagas' disease, is also an intracellular parasite, particularly of muscle tissue of the heart and alimentary tract where it produces severe disruption of organ function. As Torrealba (Universidad de Carabolo, Valencia) pointed out, it is a zoonosis which exists from the south of the US to the northern parts of Argentina and Chile. More than 150 species of mammal are carriers and serve as potential reservoirs of infection and more than 100 species of triatomid bug, the vector of transmission, are infected. In some areas of Latin America, infection rates in man are greater than fifty per cent.

A major problem for biochemists and immunologists studying parasites is obtaining adequate amounts of material. Avila (Pan America Center for Research, and Training in Leprosy and Disease of the Tropics, Caracas), who had already reported that epimastigote forms of *T. cruzi* can be grown *in vitro* in much simpler media than those currently in use, described the successful subculture of the organism in a medium containing salts, glucose, two growth factors and bovine liver catalase. The protein needed to be in its native configuration and was apparently not contaminated by purines, pyrimidines and growth factors. This observation suggests that the nutritional requirements of *T. cruzi* are markedly less exacting than those of other, non-endosymbiont-containing trypanosomatids. If confirmed, it will make life a lot easier for all *T. cruzi* investigators.

Piras and his colleagues (Centro Medico Docente La Trinidad, Caracas) made extensive use of probes such as lectins, microtubule disruptors and inhibitors of RNA and protein synthesis in their investigation of the mechanism of infection of fibroblastic cells by *T. cruzi.* The host cell membrane plays an active role in infection; in particular, surface glycoprotein(s) and an intact cytoskeleton must be present. Surface components of the parasite are also important; they may differ in each morphological form and some are possibly lacking in amastigotes isolated from cells since these are not infective. As low concentrations of actinomycin D and puromycin block infection it was suggested that both parasite and host cell membrane components need to interact and function if infection is to occur.

Considerable progress has been made in understanding the metabolism of *T. cruzi,* but few studies have been made of its regulation. Urbina and his colleagues (Universidad Central de Venezuela, Caracas) reported that *T. cruzi* contains a complete glycolytic sequence and tricarboxylic acid cycle but although glucose is metabolized, there is evidence for high rates of amino acid catabolism. Further investigations demonstrated that in *T. cruzi* there is little regulation of glycolysis by sugar phosphates or tricarboxylic acids but that amino catabolism is tightly regulated by energy charge.

Basic research in parasitology, using modern techniques, is developing rapidly in Venezuela. Most of the scientists running the programmes mentioned here have, as a result of national policy, spent some years in laboratories in Europe and North America. Clearly this policy is beginning to pay dividends. □

Weighing neutrinos: a small wait for a small weight?

from Frank E. Close

Do neutrinos have mass? The answer to this long-standing question may be answered within a few months if a proposal put forward by Alvaro De Rújula of CERN, Geneva is successful.

To provide the background to De Rújula's important idea it is worthwhile first recounting some of the history of neutrinos — mysterious particles produced in radioactive decays, which have no charge and (possibly) no mass, interacting so rarely with matter that they pass through the Earth as if it were empty space.

In β-radioactivity a neutron changes into a proton, and an electron is emitted to conserve electric charge:

$$n^0 \rightarrow p^+ + e^-$$

However, the energy and momentum of the proton and the electron do not equal that of the neutron. Rather than give up the principle of energy–momentum conservation, Pauli proposed, in 1931, that a third particle was produced in the process, and that this invisible particle (the 'neutrino') carried off the residual energy and momentum. The difference between the neutron mass and the mass of the proton plus electron would be the maximum mass that a neutrino could have and still be produced. Electrons were observed to be produced with energies up to about 1 MeV which showed that the neutrino was very light; indeed it could even have no mass at all. As no conclusive evidence for a mass has ever been found it is frequently referred to as 'massless'.

A quarter of a century passed before Cowan and Reines detected neutrinos being produced in the Savannah River Reactor in the US. These neutrinos were seen to induce the reverse reactions to those that had produced them in the first place. For their discovery they gained a case of champagne from Pauli — he had wagered that no one would ever detect so ghostly a particle!

Before turning to the ways that neutrino masses might be measured, the importance of massive neutrinos in cosmology is worth mentioning.

The density of neutrinos in the Universe should be similar to that of photons, that is at least 10^8 per nucleon. As a nucleon weighs about 10^9 eV, then neutrinos with masses even as small as 10–100 eV would provide the bulk of the Universe's mass! This would dramatically affect the expansion rate of the Universe and could

---

Frank E. Close is in the Theoretical Division of the Rutherford Laboratory, Didcot, UK.

0028-0836/81/090747-02$01.00

even slow it to the point where it stopped and then contracted to a big crunch — a replay of the big bang but in reverse. Cosmologists claim that the presently observed expansion rate probably limits the sum of the masses of all of the three known varieties of neutrinos to less than 100 eV, maybe less than 50 eV.

There have been some indirect hints that neutrinos have masses. The flux of neutrinos impinging on the Earth from the Sun's nuclear reactions (predominantly deuteron fusion $p + p \rightarrow de + \nu$) is a factor of 3 or 4 less than that expected by astrophysicists. This 'shortfall' can be understood if neutrinos have masses (see *Is the Sun still shining? Nature* **284**, 507; 1980).

The classic way to measure the neutrino mass has been through the study of the high-energy end of the spectrum of the electron produced along with the neutrino in the β-decay. At first sight this is an obvious approach — the heavier the neutrino, the lower will be the maximum available energy for the electron. The problem is that the neutron mass is not known to better than 40 eV and so one cannot resolve the neutrino mass to less than this. However, the *shape* of the high-energy tail of the electron energy spectrum depends on the mass of the accompanying neutrino (this is a kinematic property of phase space when three particles are produced as, for example, in $n \rightarrow p + e^- + \nu$).

Recently this technique has been employed in the USSR using tritium and studying the electron energy spectrum in

$$H^3 \rightarrow He^3 + e^- + \nu$$

This experiment claims the first non-zero mass result for ν — between 14 and 46 eV (V.A. Lubimov *et al. Phys. Lett.* **94B**, 266; 1980). Questions have been raised as to whether a zero mass is definitely ruled out.

In a widely attended seminar at CERN, de Rujula pointed out that there is another way that β-radioactivity produces neutrinos in a three-body final state which would be amenable to the 'shape dependence' test. Instead of producing an electron in $n \rightarrow p + e^- + \nu$ you capture an atomic electron. The nuclear capture of atomic electrons produces a continuous radiation spectrum

$$e^- + Z \rightarrow (Z-1) + \nu + \gamma$$

The photon plays the role that was previously played by the electron: measure the shape of the high-energy tail of the photon spectrum and you can infer the neutrino mass. The photon has no electrical charge and does not experience some of the scattering problems that beset charged electrons. Furthermore, detectors are available that can measure the photon energies with a precision of less than 1 eV!

If this was the whole story then one would have been doing such experiments long ago. The problem is that the event rate at the high-energy end of the spectrum tends to be so low that this approach is, at best, no improvement on the conventional technique. However, De Rújula noticed a feature of the radiation spectrum that could be exploited if a suitable nucleus existed and which would dramatically enhance the rate so allowing the experiment to be performed. Out of all the known isotopes it seems that Nature may have provided two that meet the crucial requirement! To explain this requirement we must start by detailing the nature of the radiation spectrum.

The first calculations of the intensity resulting from K-capture were made by Morrison and Schiff in 1940 (*Phys. Rev.* **58**, 24). While their calculations were in excellent agreement with the high-energy photon spectrum the observed spectra showed a considerably greater abundance of low-energy γ rays. Glauber and Martin (*Phys. Rev.* **104**, 158; 1956) showed that this enormous enhancement was due to radiative capture of electrons in L-states, the intensity peaking in the neighbourhood of the characteristic X-ray line. Thus for Fe^{55}, as an example, the peak is in the region of tens of keV while the low-intensity K capture continues all the way to the maximum available (230 keV).

If neutrinos have masses then the shape of the high-energy extreme of this distribution will be modified. Thus,although in principle we have a new way of determining the neutrino mass, the low event rate makes the method impractical. Can one find cases where the spectrum only extends for some tens of keV so that the L (or M) capture enhancement is at the high-energy end? In such circumstances the event rate will be enhanced in the very region that is relevant to the mass determination.

If you search through the atomic and nuclear tables very few examples are found. One possibility might be using

$$^{193}Pt_{78} \rightarrow {}^{193}Ir_{77} + 45\ \text{keV}$$

with a half life less than 500 years, but the most promising, studied in detail by De Rújula, seems to be

$$^{163}Ho_{67} \rightarrow {}^{163}Dy_{66} + \text{approximately zero}$$

with a half life which has not been well determined. In this latter case the high-energy end of the photon spectrum will come entirely from L,M . . . capture and have high intensity, so yielding excellent event rates.

CERN is particularly well suited to performing such an experiment.

First of all it possesses an isotope on-line separator (ISOLDE). The 600 MeV proton beam from the CERN synchocyclatron is focused on a target ion source. A beam of radioactive ions is formed by a 60 kV acceleration stage and is mass analysed by a magnet. Individual mass isotopes can then be selected by electrostatic deflection, in particular the desired Holmium isotope crucial to the electron capture experiment.

The energy spectrum of the emitted photons can be studied with an accuracy of order 1 eV, and the shape of the high-energy tail thereby precisely determined.

It is known that (at least) three varieties of neutrino exist in Nature — ν_e, ν_μ, ν_τ of which the ν_e variety is produced in the above experiments. However, each of these is, in principle, a linear superposition of mass eigenstates ν_1 ν_2 ν_3. As a result the ν_e is produced with various (unknown) probabilities to have mass m_1 m_2 or m_3. All three cases may affect the energy spectrum to produce a series of kinks. From the positions of the kinks it could be possible to determine the masses and relative probabilities for the various states.

The accumulation of isotopes is now in progress and the optimists claim that the experiment can be performed very quickly. It is possible that we have only a small time to wait before the neutrino masses are measured — unless some unforseen experimental problems arise. ☐

Woodchuck, squirrel and duck hepatitis viruses

from Arie J. Zuckerman

THE close phylogenetic relationship between human hepatitis B virus and a virus isolated from the eastern woodchuck (*Marmota monax*) has been clearly established by Cummings and his associates (*Proc. natn. Acad. Sci. U.S.A.* **77**, 1842; 1980). They have cloned the DNA of human hepatitis B virus and the DNA of woodchuck hepatitis virus in the vector γgtWES and subcloned into the kanamycin-resistant plasmid pAO1. Comparison of the recombinant DNAs with authentic virus DNAs by specific hybridization, size and restriction enzyme analysis indicated that the recombinants contained the complete genome of each virus. The nucleic acid homology between the two viral DNAs was confirmed with the cloned DNAs. Infection with either virus results in the accumulation in blood of

---

Arie J. Zuckerman is Professor of Microbiology and Director of the WHO Collaborating Centre for Reference and Research on Viral Hepatitis at the London School of Hygiene and Tropical Medicine.

0028-0836/81/090748-02$01.00

large amounts of excess virus coat protein in the form of spherical and tubular particles measuring 20–25 nm in diameter, and both viruses have 40–50 nm double-shelled or solid particles with a nucleocapsid or core containing double-stranded circular DNA with a gap and a virus DNA polymerase, and show a high degree of antigenic cross-reactivity between the cores of the two viruses, and a small region of 100–150 base pairs of nucleic acid homology as measured by liquid hybridization. The analogy between the two viruses is even closer when judged by their adaptation in their respective hosts causing persistent infection and close association with chronic liver disease and primary liver cancer.

Yet another virus related to human hepatitis B in Beechey ground squirrels (*Spermophilus beecheyi*) has been found in one region in northern California. Marion and her colleagues (*Proc. natn. Acad. Sci. U.S.A.* **177**, 2941; 1980) identified a virus in these squirrels sharing many of the unique characteristics of the human virus. Common features include virus morphology, size and structure of the viral DNA, a virion DNA polymerase which repairs a single-stranded region in the double-stranded circular genome, cross-reacting surface viral antigens, antigen–antibody systems similar to hepatitis B *e* antigen and the core antigen, and persistent infection with viral antigen present continuously in the blood. Because the ground squirrels were only bled and then released, it has not been possible to observe a disease accompanying this virus in the ground squirrel.

There is also some preliminary evidence suggesting further members of this unusual class of viruses in black-tailed prairie dogs (*Cynons ludoviccianus*) and in ducks in a province in the People's Republic of China. Virological studies, however, have not yet been completed.

As the human hepatitis B virus has not been grown in tissue culture, these phylogenetically related animal viruses may provide valuable models for the study of viral replication and the pathogenesis of chronic liver disease and primary liver cancer. □

Hominoid habitats of the Miocene

from Peter Andrews

NEW STUDIES on the palaeoecology of fossil hominoids make it increasingly likely that fossil hominoids of the early Miocene, 18 to 20 million years ago, lived in quite different habitats from those of the middle Miocene, 12 to 15 million years ago, and suggest that the way of life of the ancestors of the great apes and man will have to be reconsidered. The early Miocene hominoid species are generally found associated with fossils indicating tropical forest conditions in contrast with the middle Miocene hominoids which are associated with temperate to tropical woodland. This ecological shift is accompanied by changes in tooth morphology — in particular the development of thick enamel — and in many other characters of the skull and postcrania. The early Miocene hominoids retain mainly primitive characters while the middle Miocene species have developed many more of the derived characters shared with the living great apes and man.

Hominoids in the middle Miocene were widely distributed in Europe and Asia along a broad belt stretching from southern Europe across to south-western China. Much of this region was covered with broad-leaved sclerophyllous woodland related to a vegetation type found today only in the Canary Islands (Axelrod *Ann. Miss. Bot. Gard.* **62**, 280; 1975). The vegetation type was intermediate between the tropical and subtropical forests to the south and the moist temperate woodlands with mixed conifers and broad-leaved trees to the north. It has not been clear to which part of this spectrum the middle Miocene hominoids were adapted, because direct associations betwen hominoid species and fossil floras have not, until recently, been available. Interpretations of past habitats by analysis of the animal faunas are limited, and at the *Ramapithecus* and *Sivapithecus* localities they do no more than indicate some type of woodland. However, a recently described flora from China that comes from the same beds as a mammalian fauna containing these hominoids provides the first direct evidence of the vegetation type associated with the middle Miocene thick enamelled apes.

The flora frum Lufeng, in south-western China, shows a succession up the fossiliferous sequence from a warm humid vegetation type to cool temperate types (Sun Xiang-jun and Wu Yu-shu *Vert. Palas.* **18**, 255; 1980). The middle part of the sequence, which is where the hominoids occur, is a lignite containing pollen of both aquatic and land plants. The lignitic nature of the deposits and the presence of aquatic plants suggest swamp conditions but by far the most abundant plant forms are temperate trees and shrubs represented by 44 taxa, with 8 taxa of ferns, 11 of herbs, and 3 aquatic forms. The trees and shrubs consist of both evergreen and deciduous taxa, and the composition of the flora, although containing some sclerophyls, is closest to that of the temperate woodlands described by Axelrod as occurring to the north of the sclerophyllous belt during the middle Miocene. Woodlands of this type occur today in southern Europe to the north of the Mediterranean and Black seas. It is an unusual vegetation type in which to find primates, now largely tropical and subtropical in distribution and suggests that enamelled hominoids must have been able to survive in conditions beyond the range of most living primates.

Thick enamelled hominoids are known during the middle Miocene from Africa as well as from Europe and Asia. Faunas from Fort Ternan and Maboko Island, Kenya, have been analysed in another recent paper (Nesbit Evans *et al. J. Hum. Evol.* 10 (1), 1981), and demonstrate the presence of tropical woodland. The faunas have been analysed in two ways — by assessment of indicator species in the faunas, either singly or by combinations of species to produce habitat spectra, and by analysis of the community structure of the mammalian faunas through quantification of the diversity of ecological adaptations present in the faunas. The results of the two methods agree with each other, and with other evidence from the lower vertebrates and invertebrates, and assuming that the association between the hominoid species and the rest of the fauna is valid it can be inferred that the hominoids (*Ramapithecus* and/or *Sivapithecus*) also occupied woodland habitats during the middle Miocene in Africa.

The evidence for several early Miocene sites in Kenya is also reviewed in the same paper following the same methods. These confirm earlier results that at certain of the levels at Songhor, Rusinga Island and Koru, where the faunas are associated with hominoid species of the genera *Proconsul*, *Limnopithecus* and *Dendropithecus*, tropical forest habitat occurred.

The new data are of importance in considering the evolutionary emergence of the living great apes and man for they imply that their ancestors passed through an adaptive phase very different from their present way of life. *Sivapithecus* and *Ramapithecus* were the size of orang-utans and baboons respectively and animals of this size living in woodland habitats, whether tropical or temperate, must have been at least partly terrestial because of discontinuities in the woodland canopy. Again, because woodland habitat shows greater seasonal variation than forest the supply of fruit would have been insufficient to have played more than a minor role in the diet. In conclusion, many previous studies that have claimed an arboreal and frugivorous ancestry for the living great apes and man will need to be reconsidered, for the evidence from Middle Miocene suggests that hominoids of this period were omnivorous and partially terrestrial. □

Peter Andrews is in the British Museum (Natural History), London.

Variability of the Earth's rotation

from Frank D. Stacey

LONG BEFORE the advent of atomic clocks, it was well known that the Earth's rotation was an imperfect time-keeper. Precise time-keeping has always been one of the roles of astronomy and the stars, planets and satellites provide us with several independent or semi-independent clocks. Rather than clarifying the problem, modern measurements and recent re-analyses of earlier data have found evidence of a multiplicity of superimposed mechanisms. The difficulty is partly, of course, that some of the mechanisms involve time constants that are longer than the period of observation and so, regardless of the precision of observations, a long record is required to sort them out.

The diversity of disciplines that contribute to the study of the rotation of the Earth makes it an interesting theme for a wide-ranging discussion and, at a recent meeting*, astronomy, meteorology, oceanography, palaeontology, cosmology and the physics of the Earth's deep interior were all well represented. New data and ideas were forthcoming, as well as some thoughtful questioning of arguments supposed to be reasonably secure.

It now appears that at least some of the palaeontological data upon which we have relied for direct evidence of the relative lengths of the day, month and year in remote geological periods are very unsure. Certainly growth increments on the shells of marine organisms are well observed, but do they really indicate diurnal, monthly and annual periods, with all time increments faithfully recorded? Some of these questions have recently been brought to the fore by a controversial study of nautiloid growth rhythms (P. G. K. Kahn and S. M. Pompea *Nature* **275**, 606; 1978; see also *Nature* **279**, 452; 1979). W. W. Hughes (Andrew University, Michigan) has been examining a large number of nautiloid specimens from the British Museum (Natural History) collection. At least some organisms record the semi-diurnal lunar tide rather than the day and those observed under controlled conditions give no observable growth increments during the winter months. While we are not ready to give up hope of definitive data from growth rhythms, clearly we need much more work on control specimens and interpretation of ancient samples in the light of it before estimates of rotation rates in earlier epochs can be regarded as secure.

The gradual slowing of the Earth's rotation by tidal friction can be measured in several ways although the obvious and direct measurements of the apparent motion of distant stars with precise clocks (atomic or astronomical) is confused by shorter term fluctuations due to exchange of angular momentum within the Earth. It is agreed that tidal friction in the Earth is dominated by the dissipation of tidal energy in the sea. To extrapolate to the remote past a linear relationship, in the sense that the lunar and solar tides act independently, has generally been assumed, with dissipation proportional to the square of tidal amplitude. For most purposes this may not be too bad an approximation, in spite of the evidence that tides are turbulent and therefore at least to some extent non-linear. However, when fine details of the angular momentum exchange with the lunar and solar orbits are sought, this assumption becomes unsatisfactory. For some years T. C. Van Flandern, at the Naval Observatory in Washington, has sought, with progressively increasing precision, evidence for a time variation of the newtonian gravitational constant, G, in terms of an atomic clock determination of the lunar orbital acceleration. It is important to know whether such an observation may be confused by non-linearity of the tide because the length of the record of atomic-timed observations of the Moon appears to be approaching the point of giving a definite result. According to V. Canuto (NASA Goddard Space Flight Center, *Nature* in the press) and G. M. Blake (University of Sheffield), the bias of presently available data favours an increase in G with time rather than the decrease postulated by P. A. M. Dirac.

Evidence of short-term variations in rotation is improving rapidly. A new analysis by L. V. Morrison (Royal Greenwich Observatory) and F. R. Stephenson (Liverpool University) of the timing of occultations, with some eclipse data back to 1620, gave a much more convincing length-of-day curve than any hitherto for the period from about 1750; the data before that time were of doubtful value. There are no discontinuities like those that appeared in earlier analyses, but the occurrence of changes amounting to a few parts in 10^8 over 5 or 10 years is strikingly confirmed. Irregular motions in the Earth's core are clearly implicated although the mechanism is a subject of controversy. A new examination from French observatory going back to 1700 of the correlation between rotational changes and the geomagnetic westward drift by J. L. Le Mouël and V. Courtillot (IPG, University of Paris) showed that magnetic changes preceded rotational changes by two or three years, contrary to some questionable analyses reported earlier. This indicates a semi-independent electromagnetic coupling of the Earth's solid mantle to the outer region of the core (which carries the westward drifting features of the field, as originally proposed by E. C. Bullard), and, more strongly, to the deeper body of the core. There are clearly difficulties with this hypothesis, although it does provide a quantitative explanation of the rotation observations.

The time scale for core-induced changes in rotation rate is several years and a coupling time-constant of this magnitude is compatible with the electromagnetic torques exerted by the core-generated field on a lower mantle of conductivity $100\Omega^{-1}$ m^{-1} or so. However, the observations permit the supposition that core–mantle coupling is very tight indeed and that the apparent time constant is a feature of the core motions themselves. This supposition is necessary if the core has any role in exciting or damping the Chandler wobble. The conventional wisdom follows the Rochester–Smylie analysis of wobble coupling, which demonstrates that for the same field and mantle conductivity configuration the coupling time constant for the wobble is about 100 times as long as for the length-of-day changes. This is probably the strongest single reason for believing that tectonic displacements, including earthquakes, within the mantle excite the wobble, but S. K. Runcorn (University of Newcastle upon Tyne) keeps alive the argument that the core may be responsible for the wobble. The necessary mantle layer with a conductivity nearer to $10^4\Omega^{-1}m^{-1}$ is not well supported by observations, but such a layer does have proponents for other reasons, so this particular debate will continue for a while yet.

The smaller, but much more rapid, fluctuations in rotation must be attributed to atmospheric motions. A comprehensive new global analysis of the atmospheric angular momentum, reported by R. Hide, (Meteorological Office, Bracknell; see also *Nature* **286**, 114; 1980; **286**, 104; 1980) confirmed that major changes can occur quite rapidly, reacting on the Earth in a matter of days. The coupling is obscure but must certainly be there if the angular momentum exchange is demonstrated. A comparable analysis of the perpendicular components of atmospheric angular momentum, coupling to which would excite the wobble instead of changes in rotation rate, is promised. This reopens another of those debates that has been closed and reopened several times in the past 25 years.

What are the outstanding problems for the immediate future? If we compile a complete list, practically every problem that has ever been tackled is still on it. A personal list, restricted to four items in order of significance is (i) Adequacy of newtonian mechanics to explain the lunar orbit, (ii) Periodicities in the growth patterns of organisms exposed to a tidal cycle, (iii) Atmospheric excitation of the wobble, (iv) Lower mantle conductivity and core coupling. □

Frank D. Stacey is Professor of Applied Physics at the University of Queensland, Australia.

Isn't it Time

to have a subscription to Cell? Now in its seventh year, Cell is the prestige journal of modern biology, publishing seminal research papers on topics ranging from molecular biology to developmental biology, from cell biology to virology and genetics. Many important discoveries were first reported in Cell; current examples include such diverse reports as the first cloning of the mouse and the discovery of a splicing protein coded by an intron.

Minireviews, reviews and book reviews also are a prominent part of Cell, keeping readers abreast of research and other events in all areas. With the pace of research so fast, this part of the journal is essential reading for all researchers.

Cell is so much in demand that copies may be hard or impossible to find in the library. (Some libraries keep current issues under lock and key.) Personal subscriptions offer immediate access to the latest research and availability for future reference. *And personal subscriptions are available at less than half the regular rate.* The order form below can be used to obtain one starting with the January issue. To keep abreast of the demand to publish in Cell, there will be 15 issues in 1981.

REVIEW ARTICLE

Attenuation in the control of expression of bacterial operons

Charles Yanofsky

Department of Biological Sciences, Stanford University, Stanford, California 94305, USA

Bacterial operons concerned with the biosynthesis of amino acids are often controlled by a process of attenuation. The translation product of the initial segment of the transcript of each operon is a peptide rich in the amino acid that the particular operon controls. If the amino acid is in short supply translation is stalled at the relevant codons of the transcript long enough for the succeeding segment of the transcript to form secondary structures that allow the transcribing RNA polymerase molecule to proceed through a site that otherwise dictates termination of transcription. This site is the attenuator; the process is attenuation.

IT has long been known that RNA polymerase, with and without accessory factors, recognizes specific nucleotide sequences which signal the initiation and termination of transcription, and that this recognition is exploited in various ways in the regulation of gene expression. But during the past 10 years it has become evident that transcription termination sites can be located within as well as at the end of an operon. These internal termination sites are used in the regulation of transcription and may be used to sense features and components of metabolism that cannot be used to control initiation of transcription. This mechanism of regulation, called attenuation, can be defined as the regulation of gene expression by selective reduction of the transcription of distal portions of an operon. Regulatory studies with bacteriophage λ (refs 1–5) revealed the first case of attenuation. Two operons of this phage contain transcription termination sites which are used to control transcription of the structural genes located immediately beyond. Soon after these studies with λ a different mechanism of attenuation was discovered in the tryptophan[6] (*trp*) and histidine[7] (*his*) operons of bacteria and subsequently in several other operons of the enzymes of amino acid biosynthesis. In this review I will discuss the mechanisms of attenuation, concentrating on the tryptophan operon of *Escherichia coli*.

During the early history of studies on gene expression in amino acid biosynthetic operons, thoughts on possible regulatory mechanisms were dominated by the conceptual contributions of Jacob and Monod. The focus of investigation was therefore on the detection of a repression system and on the relative roles of amino acid and charged transfer RNAs as activators of a presumed repressor protein[8,9]. Nevertheless, Ames and his co-workers concluded that transcription of the *his* operon of *Salmonella typhimurium* was probably not governed by a repressor protein and that tRNA^{His} rather than histidine was the signal molecule[10,11]. Martin, Ames and Hartman[12], in some early speculations, proposed that it was translation of the transcript of the initial segment of the *his* operon that regulated transcription of the remainder of the operon. During the same period investigations on *trp* operon expression in *E. coli* followed a different course because there was convincing evidence that a tryptophan-activated repressor protein regulated transcription of the operon[13–19]. However, several observations were inconsistent with the view that repression was the sole regulatory mechanism of this operon. Tryptophanyl-tRNA synthetase mutants were shown to have regulatory anomalies[20–23]; addition of tryptophan to these strains did not fully depress *trp* operon expression. Moreover, Imamoto observed that the addition of tryptophan to tryptophan-starved cells not only shut down the initiation of transcription but also inhibited transcription in progress on the initial segment of the operon[24,25]. Finally, mutants lacking a functional repressor could still respond to tryptophan starvation by increasing their rate of synthesis of *trp* messenger RNA[26,27].

Definitions of terms

Leader region—The segment of an operon between the transcription start site and the structural gene(s).

Attenuator—a transcription termination site within an operon.

Transcription pause site—a region of DNA at which RNA polymerase pauses in the course of transcription.

Terminated leader transcript—The transcript terminated at the attenuator.

Termination structure—The segment of the leader transcript that is thought to be recognized as a termination signal by RNA polymerase.

Leader peptide—The short peptide encoded in the terminated and readthrough transcripts of the leader region.

These findings suggested that repression was not the sole means of regulating the *trp* operon of *E. coli*. Ultimately, two observations forced consideration of alternative regulatory schemes. Among a set of *trp* deletion mutants, in which both deletion termini were within the transcribed region of the operon, some had an unexpected sixfold increase in expression of the remaining genes of the operon[6,28]. Since repressor control was not affected by these deletions, what must have been deleted was a site distinct from the operator but which was also used to regulate transcription of the operon. The second observation was that within the mRNA sequences produced *in vivo* from the 5′ end of the *trp* operon, oligoribonucleotides corresponding to the first 140 base pairs of the operon were several times more abundant than those derived from more distal segments[29,30]. These findings suggested that there was a site of transcription discontinuity, possibly a stop site, in the initial segment of the operon[6].

When transcription of the initial segment of the *trp* operon was studied *in vivo* and *in vitro*[28,30–34] it became apparent that a transcription termination site was located before the structural genes of the operon. Moreover, starving bacteria of tryptophan reduced termination of transcription at this site[27,35]. Kasai provided convincing evidence of an equivalent site of regulation of transcription of the *his* operon of *S. typhimurium*[7]. He called regulation at this site 'attenuation', the term now generally used to describe regulation by transcription termination.

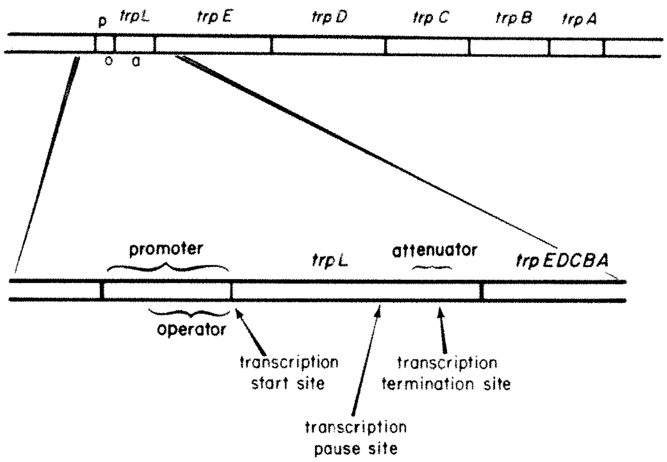

Fig. 1 The regulatory and structural gene regions of the *trp* operon of *E. coli*. Transcription initiation is controlled at a promoter–operator. Transcription termination is regulated at an attenuator, in the transcribed 162-base pair leader region, *trpL*. All RNA polymerase molecules transcribing the operon pause at the transcription pause site before proceeding further.

Features of the tryptophan operon and its regulatory region

The *trp* operon of *E. coli* consists of a transcription regulatory region and five structural genes encoding the polypeptides that catalyse the terminal sequence of reactions in tryptophan formation[36,37] (Fig. 1). The operon is approximately 7,000 nucleotide pairs long, and each cistron of the polycistronic transcript of the operon seems to be translated equally. The initiation of transcription is regulated at an operator site located within the promoter region of the operon[15–20,38,39]. A tryptophan-activated repressor protein, the product of the unlinked regulatory gene *trpR*, regulates initiation by controlling the access of RNA polymerase to the promoter[39–41]. The transcription termination site or attenuator (see below for definitions of terms) is located within the 162-nucleotide pair transcribed leader region, *trpL*, preceding the first major structural gene. There is also a transcription pause site within *trpL* (M. Winkler and C. Yanofsky, in preparation). A possible role for this site will be discussed below.

Repression rather than attenuation exerts the greater quantitative effect *in vivo* on transcription of the structural genes of the operon; repression can reduce transcription up to 70-fold[42] while attenuation can only reduce it 8–10-fold[6,35]. Because tryptophan starvation increases expression by relieving both repression and attenuation, transcription of the *trp* operon of *E. coli* can be regulated over a range of about 600-fold. For a more thorough discussion of all aspects of regulation of tryptophan biosynthesis in bacteria the reader is referred to the excellent reviews of Crawford and Stauffer[43] and Platt[37].

Attenuation

In addition to locating the attenuator in the distal segment of *trpL*[6,28], mutants have also provided clues to the mechanism of attenuation. Mutations altering tryptophanyl-tRNA synthetase, tRNA^{Trp}, or a tRNA^{Trp} modifying enzyme and thereby reducing the efficiency of translation of Trp codons, were also found to decrease the termination of transcription at the *trp* attenuator[44–47]. This suggested that attenuation involved the translation of Trp codons rather than simply the recognition of changes in the tryptophan concentration. Attenuation in the *trp* operon is also affected by mutations of functionally important sequences in the leader region. Finally, mutations affecting RNA polymerase and the transcription termination protein rho also affect termination of transcription at the *trp* attenuator[47,48]. The role of rho, if it has one, in transcription termination at the *trp* attenuator is unclear.

The leader transcript

Both *in vivo* and *in vitro* transcription studies established that transcription can be terminated in the leader region of the *trp* operon of *E. coli*[28,32]. Termination occurs at approximately the same position *in vivo* and *in vitro* to give a leader transcript approximately 140 nucleotides in length[31]. The DNA region within which RNA synthesis stops is A+T rich and is immediately preceded by a G+C-rich region that exhibits dyad symmetry. This arrangement is typical of many prokaryotic transcription termination sites[49] and both regions are implicated in the transcription termination event. The question is how, at the *trp* operon attenuator, can tryptophan deficiency be sensed and communicated to the transcribing RNA polymerase molecule, allowing it to transcribe beyond the attenuator into the structural genes of the operon?

Ribosome binding experiments carried out with the 140 nucleotide *trp*-leader transcript yielded the unexpected result that ribosomes protect a 20-base segment of the early portion of the transcript from nuclease attack[50] (Fig. 2). A potential AUG start codon is located in the centre of the protected region. Were translation initiated at this start codon and terminated at the next stop codon (UGA at nucleotides 69–71), a 14-residue peptide would be synthesized with adjacent tryptophan residues near its distal end (Fig. 2). The presence of tandem tryptophan residues in this predicted 14-residue peptide was tantalizing because tryptophan is a rare amino acid in the proteins of *E. coli*, generally being used only once in every 100 amino acid residues. (The amino acid constitution of the predicted leader peptides now known to be specified by other biosynthetic operons (Fig. 3) turned out to be even more striking—see below.) The presence of the tandem tryptophan residues in this small peptide encoded in the leader region suggested a possible role for tRNA^{Trp} in the regulation of transcription termination at the *trp* operon attenuator[33]. It was hypothesized that in cells starved of tryptophan a ribosome translating the leader transcript would stall at either of the two Trp codons. Only with sufficient tryptophan would the ribosome complete the entire leader peptide. The final position of the translating ribosome on the transcript could then be the distinctive feature communicated to the transcribing polymerase in the regulation of termination at the attenuator. It was reasonable to consider this hypothesis since in prokaryotes transcription and translation proceed in concert. These considerations raised two crucial questions. Is the potential AUG start codon within the ribosome-protected region (the ribosome binding site) actually used as a site of translation initiation, and, is the existence of adjacent Trp codons in the transcript coincidental?

The *trp* leader ribosome binding site was shown to be an efficient site for the initiation of translation by fusing it to a structural gene or a portion thereof and demonstrating the synthesis of fused polypeptides[51,52]. Since the leader ribosome binding site is used, we must presume that our inability to detect

Fig. 3 The predicted amino acid sequences of the leader peptides of the *pheA*, *his*, *leu*, *thr* and *ilv* operons of *E. coli* or *S. typhimurium*. Amino acids which regulate the respective operons are in italicized capitals and are underlined. For references see text.

the leader peptide is due to its instability. That the leader peptide as such does not have a regulatory role is indicated by complementation analyses[53].

The significance of the tandem Trp codons in the *trp* leader transcript of *E. coli* is supported by their presence also in the *trp* leader regions of *Shigella dysenteriae*, *Salmonella typhimurium*, *Serratia marcescens*[34,54,55] and *Klebsiella aerogenes* (M. Blumenberg and C. Yanofsky, unpublished). The predicted amino acid residues of these *trp* leader peptides are also conserved in the Arg-Thr-Ser sequence that follows the adjacent Trp residues but not in the sequence that precedes it. More importantly, the predicted leader peptides of other amino acid biosynthetic operons that are regulated by attenuation also are rich in the amino acid which is the end product of the appropriate pathway (Fig. 3). Hence, in a bacterial cell starved of any of these amino acids, the ribosome translating the leader transcript of the respective operon would stall over the appropriate codon rather than move to the leader transcript stop codon. Figure 3 reveals that the number as well as the location of the distinctive amino acids varies, presumably reflecting quantitative differences in regulation of the different operons.

If ribosome stalling at the Trp codons of the transcript of the leader region were sufficient to prevent the termination of transcription at the *trp* attenuator, then would stalling anywhere in the coding region of the transcript have the same effect? Starving *E. coli* mutants for each of seven amino acids encoded in the *trp* leader transcript (Met, Val, Leu, Gly, Trp, Arg and Thr) and two that are not (His and Pro)[53] revealed that the starvation response was relatively specific. Only cells depleted of Trp or Arg exhibited reduced termination of transcription at the *trp* attenuator. Comparable starvation experiments with the *trp* operon of *S. marcescens* (I. Stroynowski and C. Yanofsky, unpublished) demonstrated that starvation for His, the second residue before Trp in the leader peptide, as well as for Trp or Arg, reduced the termination of transcription at the *trp* attenuator. These observations suggested that ribosome stalling in the vicinity of the Trp codons is sufficient to exert a regulatory effect.

This conclusion led to the question of how amino acid starvation and presumed ribosome stalling are communicated to the transcribing polymerase. Hoping to answer this question we scrutinized the transcript of the leader region, searching for potential secondary structures that might relate to the transcription termination event. This search was prompted by the suggestion of Marty Rosenberg, on the basis of sequence analyses with a terminated transcript of bacteriophage λ[56], that base-paired segments in RNA may serve as a signal in the transcription termination event. Limited RNase T_1 digestion of the 140-nucleotide long *trp* leader transcript revealed extensive secondary structure in the transcript; many phosphodiester bonds in the latter half of the transcript were relatively resistant to nuclease attack[33]. Also, certain fragments in partial digests of the transcript were observed to migrate together during electrophoresis in non-denaturing gels[57]. Presumably they did so because they were base-paired. Analyses of the nuclease-resistant RNA fragments, as well as computer matching of complementary sequences, indicated that the transcript contains the two hairpin loops shown in Fig. 4 (left). For simplicity, we designate the four strands participating in these structures 1–4 (Fig. 4). We observed that strands 1 and 2 were paired and that strand 3 remained covalently attached to strand 4. The calculated free energies of these base-paired structures are given in Fig. 4. Note that strand 1 contains the adjacent Trp codons and that structure 3:4 resembles other hydrogen-bonded hairpin structures that immediately precede the 3′ ends of terminated transcripts. Inspection of the sequences of the paired regions revealed an interesting feature—that strand 2 could potentially pair with strand 3 as well as with strand 1[33] (Fig. 4, right). This led to the suggestion that alternative secondary structures in the *trp* leader transcript might provide the termination or read-through signals that RNA polymerase recognizes.

We could imagine, as shown in Fig. 5, that the position of the ribosome on the transcript determines which one of the alternative RNA secondary structures would be formed[46,57]. For example, a ribosome stalled at the Trp codons or the Arg codon by a shortage of either amino acid would sterically block 1:2 pairing, thereby allowing strand 2 to pair with strand 3 as soon as strand 3 had been synthesized. By the time strand 4 had been synthesized its potential pairing partner, strand 3, would be base-paired and unavailable, preventing the formation of termination structure, 3:4. If 3:4 did not form and if, as we also believe (see next section), the 3:4 structure is the termination signal that RNA polymerase recognizes, then the transcribing polymerase would not stop at the attenuator. Consequently, the structural genes of the operon would be transcribed, leading ultimately to the biosynthetic correction of the tryptophan deficiency. If, however, a ribosome stalled at the Thr codon or reached the stop codon, strand 2 would be sterically prevented from pairing with strand 3 and thus 3:4 would be free to form and signal transcription termination. If the ribosome stalled at the Gly codon strand 1 would pair with strand 2, thereby preventing 2:3 pairing and facilitating pairing of 3 with 4. According to this scheme it is the location of the ribosome on the transcript of the *trp* leader region that determines which alternative RNA secondary structure forms. This, in turn, directs RNA polymerase to terminate transcription or to read through

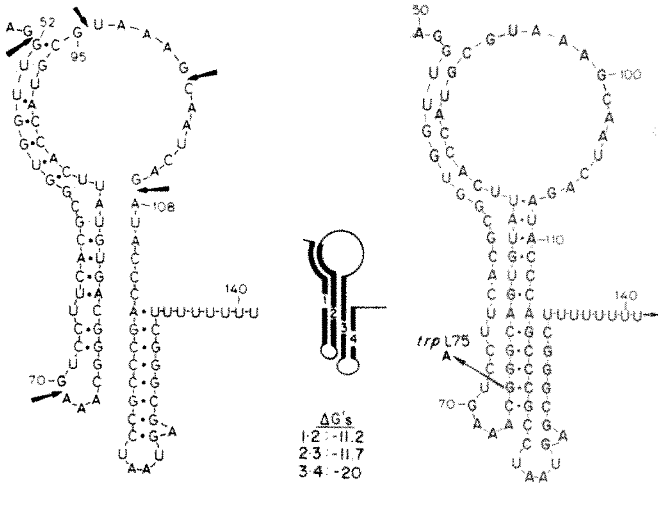

Fig. 4 Secondary structure alternatives in the *trp* leader transcript. In the large structure on the left the two base-paired structures that are detected *in vitro* are presented. The arrows indicate the sites of RNase Tl attack. The G-bonds in the hydrogen-bonded regions are not cleaved, presumably because the Gs are base paired. In the large structure on the right an alternative secondary structure is shown. Formation of this structure is thought to prevent transcription termination at the attenuator. For simplicity we designate the transcript segments that participate in these hydrogen-bonded structures strands 1–4 (see centre inset). The *trp* codons are in strand 1. The *trpL75* mutation is indicated.

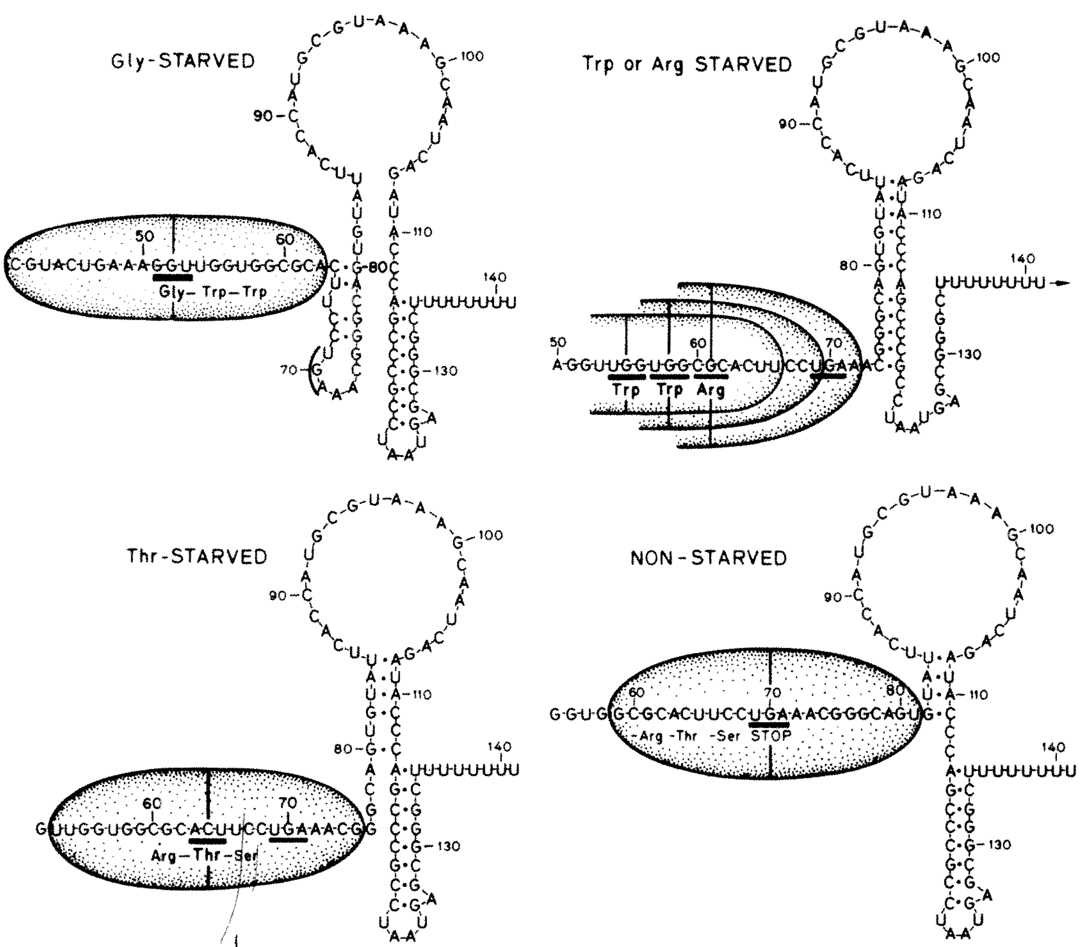

Fig. 5 Schematic representation of ribosome position on the *trp* transcript in cells starved of Gly, Trp, Arg or Thr, or cells that are not starved. It is proposed that a ribosome stalled over one of the codons of the transcript sterically blocks about 10 nucleotides on the downstream segment of the transcript, thereby determining which alternative secondary structure will form during transcription. Only when cells are starved of Trp or Arg is the ribosome positioned so that structure 2:3 will form. The existence of structure 2:3 could prevent pairing of 3 with 4 while 4 is being synthesized. It is assumed that transcription terminates at the attenuator only when structure 3:4 is formed during transcription.

into the structural genes of the operon. With this model for reference we can explain why the Arg-Thr-Ser codon sequence that follows the tandem Trp codons of *trp* transcripts is conserved in the enterobacteria. The Arg-Thr-Ser coding region is within the segment of strand 1 that can base pair with strand 2 (Figs 4, 5). Conservation of this region presumably reflects a requirement for this pairing capability.

Mutations in the leader region of the *trp* operon

Two classes of termination-defective *trp* leader mutants have been isolated. One type terminates transcription at less than the normal frequency and therefore operon expression is increased[58,59]. The base-pair changes in approximately 30 mutants of this type have been determined and, with one exception, all are in the segment of the leader region that corresponds to the 3:4 base-paired RNA structure (Fig. 6). Each of these base-pair changes reduces the predicted stability of the 3:4 structure by about 50%. All of these mutations affect the central G·C base pairs of the structure (Fig. 6), which of course have the greatest effect on stability of the 3:4 structure. *In vivo*, each of these mutations results in a two- to fourfold increase in operon expression. When restriction fragments bearing these mutations are transcribed, 40–70% of RNA polymerase molecules read through the attenuator. With a wild-type template only 5% do so. Clearly, these single mutant changes markedly influence the termination of polymerase activity. Largely on the basis of these findings we believe that the hydrogen-bonded 3:4 structure is the termination signal that the transcribing polymerase recognizes. Consistent with this conclusion is the additional observation[33] that when transcription is carried out *in vitro* with ITP substituting for GTP, transcription is no longer terminated at the attenuator, presumably because I = C base-paired RNA is less stable than G ≡ C base-paired RNA. Similar *in vitro* transcription studies with other base analogues that affect RNA secondary structure also suggest that a stable 3:4 RNA secondary structure is necessary for transcription termination[60].

A role for the A + T-rich as well as the G + C region of the attenuator in termination of transcription is suggested by our discovery of a termination-defective *trp* leader mutant with a single base-pair change in the A + T-rich region of the attenuator[58]. In addition, a deletion mutant exists in which the distal four A + Ts of the A + T-rich region are replaced by a foreign sequence[31]. This change eliminates transcription termination at the attenuator *in vitro* and reduces it *in vivo*[31,60]. Certain mutants altered in the β subunit of RNA polymerase are also aberrant in termination of transcription at the *trp* attenuator (C. Yanofsky and V. Horn, unpublished). In one class termination is partially relieved, while in a second, termination is more frequent. These mutations influence the termination of transcription only in strains which can form the 3:4 base-paired structure, strengthening the conclusion that this structure is the termination signal that is recognized by RNA polymerase.

There are also mutations in the *trp* leader region which increase termination at the attenuator *in vivo*[53]. Some mutations of this type have a second interesting and important property; they prevent the relief from termination that is normally associated with tryptophan or arginine starvation[53]. This observation provides the strongest evidence for our model of attenuation. In one of these mutants, *trpL29*, which has been isolated on two separate occasions, the AUG start codon for the leader peptide is replaced by AUA, a change which would prevent efficient translation of the leader transcript. Since strains with this mutation do not respond to tryptophan starvation by relieving termination, a prediction of our model—that a ribosome must move to the Trp codon region of the transcript for transcription termination to be relieved—is supported. A second type of mutant, *trpL75* (Fig. 4), of which there have also been two isolates, has a G → A change at position 75 in the leader region. Since this change essentially eliminates the pairing of strand 2 with strand 3, thereby leading to the formation of the 3:4

termination structure, our model explains why termination occurs despite tryptophan starvation. These considerations support two important features of our model: first, that a ribosome must translate the transcript at least to the first Trp codon for termination relief, and second, that pairing of strand 2 with strand 3 is also required for this relief. Thus, these observations strongly suggest that alternative secondary structures in the RNA transcript determine whether or not termination will occur at the *trp* operon attenuator.

Why do these two types of mutants exhibit increased termination of transcription at the attenuator *in vivo*? In the wild-type bacterium we assume that operon expression provides for some transcription readthrough, even in the presence of excess tryptophan[58]. This could be due to rapid dissociation of the translating ribosome from the stop codon of the transcript, allowing the 2:3 alternative structure to form. If this happens, formation of the 3:4 structure would be prevented and the transcribing RNA polymerase molecule would continue into the structural genes of the operon. This model can explain the increased termination observed *in vivo* in the two types of termination mutants. The AUA translation initiation-defective mutant would, during transcription, form structure 1:2. This would prevent pairing of strand 2 with 3, thereby promoting the formation of termination structure 3:4. In mutant *trpL75*, pairing of strand 2 with strand 3 is presumably defective. Hence, despite ribosome dissociation from the stop codon, strand 2 could not pair with strand 3, and therefore 3:4 would form more often. Thus, the increased termination of transcription observed in these mutants can be readily accommodated within our model.

Also consistent with our model is the observation that neither mutant change affects transcription termination at the attenuator *in vitro*[58].

The leader pause site

When restriction fragments containing the *trp* promoter are transcribed we observe the 140-nucleotide terminated leader transcript as the major product along with a small amount of a readthrough transcript. However, at early times during a single round of transcription, a third, major transcript is seen (M. Winkler and C. Yanofsky, unpublished). This species—which we call the pause transcript—is 90 nucleotides long and has at its 3′ terminus the sequence that could form the 1:2 base-paired structure (Fig. 4). Enhancement of pausing at this site when BrUTP replaces UTP (P. J. Farnham and T. Platt, unpublished) supports this proposal since numerous U's are present in the 1:2 stem. Kinetic studies indicate that every polymerase molecule that transcribes the initial segment of the leader region pauses at the 'leader pause site'. Eventually, these polymerase molecules resume transcription so that the pause transcript grows to become either the terminated transcript or the readthrough transcript. The position of the pause site in the leader region suggests that it could be used to synchronize ribosome attachment, movement and positioning on the leader transcript relative to the transcribing RNA polymerase molecule. The polymerase molecule might be held at the pause site until the translating ribosome reached a particular position on the transcript. Thereafter, the polymerase molecule would resume transcription and the translating ribosome would reach the positions on the transcript that favour one or the other of the alternative RNA secondary structures.

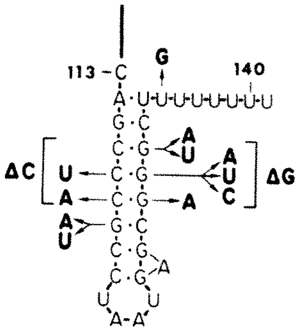

Fig. 6 Base pair changes in the *trp* leader region that relieve transcription termination at the attenuator. The changes in the transcript are shown; all are in the 3:4 structure and reduce its stability except the single U→G change at position 135.

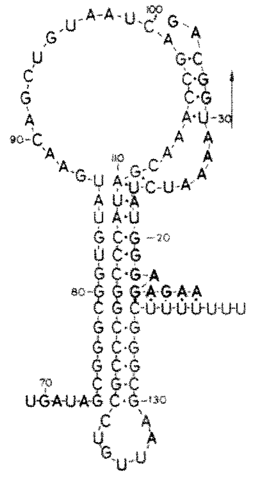

Fig. 7 Pairing of the leader ribosome binding site with the distal portion of the *trp* leader transcript of *S. typhimurium*. Note that both the Shine–Dalgarno region and the start codon region are hydrogen bonded to the distal segment of the transcript. Pairing of the indicated RNA segments has been demonstrated experimentally (K. Brown and C. Yanofsky, unpublished).

The leader ribosome binding site

Perusal of the sequences of the *trp* leader transcripts of various organisms and the results of secondary structure studies with these transcripts suggest an additional feature of the attenuation process. When the secondary structures formed in *trp* leader transcripts from different enterobacteria were analysed, another base-paired species was detected in addition to the 1:2 and 3:4 structures (K. Brown and C. Yanofsky, in preparation). This species contains an early segment of the transcript—the region containing the leader ribosome binding site—base-paired to a distal segment (Fig. 7). The calculated free energy for this base-paired segment is about $-32\ \mathrm{kcal\ mol^{-1}}$. If this pairing occurs *in vivo* the distal segment of the transcript could block the leader ribosome binding site, thereby preventing additional rounds of translation. Thus, once the decision was made to terminate transcription or to allow readthrough at the *trp* attenuator, additional translation of the peptide coding region would be prevented by masking the leader ribosome binding site. Sequence arrangements that allow pairing with the leader ribosome binding site may be a common feature of the structure of transcripts of operons regulated by attenuation (ref. 54 and M. Blumenberg and C. Yanofsky, unpublished). This situation is reminiscent of the masking of ribosome binding sites in RNA phages[61,62].

Summary of the mechanism of attenuation

Our current view of the events accompanying attenuation in the *trp* operon is as follows: a RNA polymerase molecule that escapes repressor control initiates transcription of the operon.

Soon after the segment of the transcript containing the leader ribosome binding site has been synthesized a ribosome attaches. Synthesis of the leader peptide begins while transcription of the later regions continues. The transcribing RNA polymerase molecule reaches the transcription pause site where it remains briefly, allowing the translating ribosome to approach. When RNA polymerase resumes transcription, the translating ribosome either stalls at one of the Trp codons, if the cell is deficient in tryptophan, or, if tryptophan is plentiful, moves to the translation stop codon. The position of the ribosome on the transcript determines which alternative RNA secondary structure forms. Only if structure 3:4 forms does the polymerase terminate transcription at the attenuator. Whether termination occurs or not, the leader ribosome binding site is then blocked by pairing with a transcript segment.

The interpretation given above presumes that changes in the secondary structure of transcripts mediate the regulatory response. This has not been proved! Structural studies on transfer RNAs have established that interactions other than hydrogen bonding contribute to three-dimensional form. Furthermore, a regulatory role for the DNA template has not been excluded. We should therefore keep open the possibility that other interactions also participate in establishing the informational transcript or template structures that are crucial in attenuation.

Attenuation in other amino acid biosynthetic operons

Extensive regulatory studies have been performed with the *his* operons of *S. typhimurium* and *E. coli*. This operon was the first gene cluster for which there was convincing evidence suggesting that charging of a transfer RNA had a regulatory role[8]. The leader regions of the *his* operons of *S. typhimurium* and *E. coli* have been sequenced[63,64] and appear to have structures resembling that of the *trp* operon. A potential ribosome binding site is situated in the leader transcript sequence, which, if used, would give a 16-residue peptide containing 7 adjacent His residues. A G+C-rich region with dyad symmetry is located somewhat beyond and is followed by an A+T-rich segment within which transcription termination probably occurs. The transcript segment corresponding to the G+C-rich region could form a stable stem and loop that could serve as a termination signal. A potential alternative competing secondary structure can be drawn for the transcript that could prevent formation of the presumed termination structure, depending on the location of the ribosome translating the leader peptide-coding region[63–65]. *In vitro* studies have implicated translation in the regulation of transcription of the *his* operon[66]. In addition, analyses with regulatory mutants altered at key positions in the *his* leader region provide insight into the parts played by different segments of this region or more likely, the corresponding transcript[65]. An ochre nonsense mutation in the leader peptide-coding region decreases operon expression to the extent that the corresponding mutant is a His auxotroph. This observation suggests that translation of at least the initial part of the leader peptide coding region is essential for operon expression. Suppression of the ochre mutation increases *his* enzyme levels and restores the His$^+$ phenotype. A second mutation conferring His auxotrophy occurs just beyond the translation stop codon for the leader peptide. Oddly enough, although this mutation does not introduce an amber codon, it is suppressed by amber suppressors. Apparently, the mutation prevents formation of the competing RNA structure, resulting in more efficient termination at the attenuator[65]. Presumably, the amber suppressors increase operon expression by allowing the translating ribosome to translate the leader peptide stop codon and disrupt the transcript termination structure[65]. One verified prediction of this interpretation was that amber suppressors would increase expression of the wild-type *his* operon.

Finally, a deletion that removes part of the termination structure increases operon expression. Thus, all aspects of attenuation in the *his* operon are similar to those of the *trp* operon, suggesting that attenuation is used in much the same way.

The *thrA$_1$A$_2$BC* and *ilvGEDA* operons of *E. coli* have an additional feature readily accommodated by the attenuation mechanism regulating amino acid biosynthetic operons[67–69]. Expression of these two operons is influenced by two and three amino acids, respectively (multivalent control). Obviously, if a leader transcript contains multiple codons for two or three amino acids in the critical pairing regions, the operon could respond to starvation for any one of these amino acids. The sequences of the leader regions of the *thr* and *ilv* operons suggest that this is exactly what occurs. The *thr* leader region encodes a peptide rich in Thr and Ile residues (Fig. 3); it contains a G+C-rich, A+T-rich region resembling other terminators, and its sequence predicts the formation of alternative, competing paired transcript structures that would be influenced by ribosome position on the transcript[67]. Mutants establish that the G+C-rich region is essential for the termination of transcription. The *ilvGEDA* operon is a more extreme example of multivalent control. It is regulated by changes in the extent of charging of Val, Ile and Leu tRNAs[8]. The leader region codes for a putative 32-residue peptide with multiple Ile, Val and Leu residues and contains adjacent G+C- and A+T-rich regions at which transcription is terminated *in vitro*[68,69]. Mutually exclusive secondary structures have been predicted for the transcript. Their role in the termination of transcription is supported by the finding that substitution of ITP for GTP in the *in vitro* transcription reaction prevents termination. The potential secondary structures in the transcript are complex, perhaps reflecting the need to respond to starvation for any one of the three amino acids. Stalling of more than one ribosome on the transcript may be required for maximum relief of termination[68].

The *leu* operon of *S. typhimurium* has a leader region containing all the features found in the other amino acid operons[70,71]. A 160-nucleotide terminated transcript is produced *in vitro*. The transcript codes for a 28-residue peptide containing 4 contiguous Leu residues. Alternative secondary structures can be predicted for the transcript, including a termination structure, a competing structure and a third structure that could prevent formation of the competing structure if translation of the transcript stopped early in the peptide-coding region. Again, substituting ITP for GTP in the *in vitro* transcription reaction prevents termination.

The Leu codons of the transcript are so positioned that ribosome stalling in the Leu codon region would promote formation of the RNA structure that is the alternative to the termination structure.

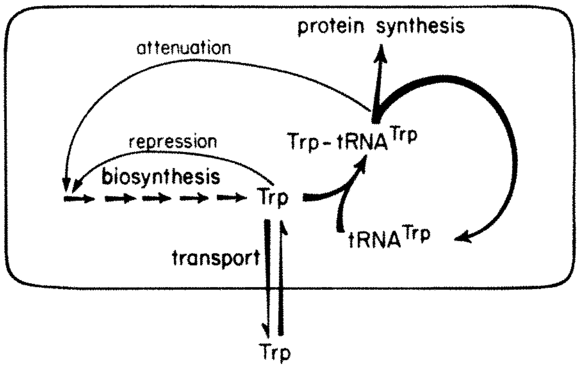

Fig. 8 Metabolic processes involved in tryptophan synthesis and utilization. The existence of the two transcription control mechanisms for the *trp* operon allows the bacterium to sense both the intracellular concentration of tryptophan and the extent of charging of tRNA^{Trp}.

The *pheA* operon of *E. coli* is a single gene operon containing a leader region with all the features seen in other amino acid operons controlled by attenuation[72]. A terminated transcript is produced *in vitro* and the site of termination is a typical termination region. The predicted *phe* leader peptide is 15 residues in length and contains 7 Phe residues in the last two-thirds of the peptide. Stable RNA secondary structures can be drawn for the *phe* transcript. Ribosome stalling over the Phe codons of the transcript could prevent formation of the transcript termination structure.

Thus, despite considerable differences in the sequences of leader regions of the *trp*, *his*, *thr*, *ilv*, *leu* and *phe* operons, the predicted structures of each of their transcripts allows the same mechanism of attenuation. When we compare the specific elements of repression systems with those of attenuation as they are used in amino acid biosynthetic operons, it is obvious that from the point of view of information content attenuation is a more economical regulatory mechanism. The unique regulatory information of attenuation is provided by the sequence of 50 or so base pairs of the leader region of each operon. This information is sufficient to be interpreted in terms of the appropriate regulatory response by the transcriptional and translational machinery of bacterial cells.

Conclusions

The existence of two mechanisms for regulating transcription of the *trp* operon leads one to wonder what advantage it is to the organism to have this apparent duplication of regulatory effort. The two mechanisms clearly allow similar responses to the same physiological situations. A possible explanation can be offered by considering the various metabolic reactions involved in the biosynthesis and utilization of tryptophan (Fig. 8). The repression system, by responding to tryptophan exclusively, is tailored to titrate the intracellular concentration of this amino acid. This concentration depends on several factors: first, tryptophan availability in the environment of the bacterium and its entry into the cell via transport systems; second, the rate of tryptophan biosynthesis; and third, the utilization of tryptophan for protein synthesis. By gauging the intracellular concentration of tryptophan, repression is particularly well suited to regulate expression of the operon in response to changes in the availability of tryptophan from the environment. We believe this to be its primary purpose. Attenuation is influenced by the extent of charging of tRNA^{Trp}. The relative concentrations of charged and uncharged tRNA^{Trp} are determined by several factors: the intracellular tryptophan concentration, the amount and activity of tryptophanyl-tRNA synthetase, the amount of tRNA^{Trp} and, perhaps most importantly, the overall rate of protein synthesis. It is this last factor that we believe provides the best explanation for attenuation. If a cell becomes deficient in one of the other amino acids the tRNA^{Trp} pool will become fully charged, resulting in maximal termination at the attenuator. Conversely, if a cell suddenly begins to synthesize proteins rapidly and tryptophan is in short supply, the tRNA^{Trp} pool will be relatively uncharged and there will be little or no termination at the attenuator. Thus, the attenuation mechanism nicely regulates expression of the operon relative to the overall rate of protein synthesis. The combined action of the two regulatory mechanisms enables the bacterium to recognize and respond to the principal external and internal events relevant to expression of the operon.

If it is advantageous to have two transcription control mechanisms for the *trp* operon of *E. coli*, why is attenuation the sole transcription control mechanism used to regulate expression of other amino acid biosynthetic operons such as the *his*, *leu* and *thr* operons[65,67,70]? The explanation for this apparent contradiction, I believe, is provided by our recent finding that two other operons are regulated by the *trp* repressor. These are the *aroH* operon, specifying one of three enzymes that catalyse the initial reaction in the common pathway of aromatic amino acid biosynthesis[73], and the *trp* repressor operon, encoding the *trp* aporepressor[40,74]. In both cases, tryptophan-activated repressor binds to the operator–promoter region of the operon and inhibits transcription initiation. However, the operators in these three operons are at different locations in their respective promoters[40]. This finding is consistent with the hypothesis that these operators evolved independently. Thus, we might speculate that in an organism ancestral to *E. coli* and other enterobacteria, the *trp* repressor might have been used to regulate *aroH* expression while the *trp* operon was regulated by attenuation alone. Subsequently, by very few mutations, an operator may have evolved in the *trp* operon, thereby permitting additional control over transcription of this operon. We suggest, therefore, that two regulatory mechanisms now exist for controlling transcription of the *trp* operon of *E. coli* because it was advantageous to the organism to have evolved a *trp* repressor binding site in this operon so that it could exploit the availability of the *trp* repressor.

Extensions

Attenuation as used in the regulation of amino acid biosynthetic operons is only one of several ways in which gene expression could be controlled through the termination of transcription. Alteration or modification of RNA polymerase, as is presumed to occur when it interacts with the N protein of bacteriophage λ[75–78], or interference with the action of proteins participating in transcription termination[78], are additional attenuation mechanisms. Transcription termination sites could also be used simply to reduce transcription of a gene relative to a leader segment or a preceding gene in the same operon. The *trpR* operon, specifying the *trp* aporepressor, has a termination site in its leader region which may function in this manner[40]. Similarly, the termination site located between *rplL* and *rpoB* in the *rplJL–rpoBC* operon may be used to regulate expression of the two RNA polymerase structural genes relative to the ribosomal protein genes[79]. Inadvertent attenuation also occurs when translation is prematurely terminated within one of the structural genes of a polycistronic operon. Here, in what is termed translational polarity[80], the termination of transcription reduces the transcription of distal genes[81]. In addition to these examples, one could imagine many interactions that would alter the secondary structure of RNA and thereby influence termination. Transcriptional pausing[82–84] should also be considered a mechanism of attenuation. Pause sites could conceivably be used to set the rate of transcription of a gene or operon below that attainable by polymerase–promoter interaction alone. Pause sites may thus fix the maximum rates of transcription. Studies on pausing in phage T7 and in the *trp* operon suggest that pausing can serve different regulatory roles[83,84] (M. Winkler and C. Yanofsky, unpublished). Finally, attenuation may not be limited to bacteria and their viruses but may also occur in animal viruses. In vesicular stomatitis virus (VSV), transcription decreases in an oriented manner at or near the junctions of neighbouring genes, resulting in a cumulative reduction in distal gene expression[85]. In adenovirus and VSV transcription short leader transcripts are accumulated[86,87], an observation suggesting attenuation. It is apparent from the examples cited that transcriptional attenuation is accomplished in diverse ways. We presume that these mechanisms bring into regulatory focus those cellular processes and components that cannot readily participate in the mechanisms that control the initiation of transcription.

Perusal of the reference list will convince the reader that the model developed in this article was based on the work of a large number of collaborators. To each, I express my sincerest appreciation for sharing in this adventure. I also thank my current co-workers and Irving Crawford, Terry Platt, Howard Zalkin and George Stauffer for their helpful comments, and the NSF, the USPHS and the American Heart Association for their continuing support. C.Y. is a Career Investigator of the American Heart Association.

R. S. Booth, I. W. A. Browne, D. Walsh & P. N. Wilkinson

University of Manchester, Nuffield Radio Astronomy Laboratories, Jodrell Bank, Macclesfield, Cheshire SK11 9DL, UK

Very long baseline interferometry (VLBI) observations of the double QSO 0957+561 have revealed radio fine structure in the two 'image' components A and B. The structures are similar, both of the 'core–jet' type typical of many compact extragalactic radio sources. The shapes of the images put strong constraints on the mass distribution responsible for the gravitational imaging.

THE twin QSOs 0957+561A, B are widely believed to be images of a single QSO produced by the gravitational lens effect[1]. The lens has been identified with an 18.5 mag elliptical galaxy in a distant cluster[2–5]. The similarity of the optical spectra of the images has been confirmed[6,7] and the flux ratio of the images has been shown to be the same over a wide range of frequencies covering the radio to UV parts of the spectrum[8–17].

The asymmetry of the geometry of the 'images' A and B with respect to the galaxy indicates that the lens action cannot be modelled by a spherical mass distribution[3]. The gravitational

0028-0836/81/090758—05$01.00

field of the surrounding galaxy cluster and the (non-spherical) mass distribution of the elliptical galaxy also determine the geometry of the images. In previous VLBI observations[10] we showed that the radio components A and B both have compact structure on a scale size of <20 marc s. We now report the results of more extensive and more sensitive VLBI observations at two frequencies, using inteferometers with resolutions ranging from 60 to 1 marc s.

Observations

We have made two sets of VLBI observations of the double QSO with the 2-MHz bandwidth Mark II recording system, using a transatlantic baseline and the large antennas available in the European VLBI network. On 9–10 January 1980 we observed at 4,996 MHz using the Max-Planck-Institüt für Radioastronomie (MPIfR) 100-m telescope at Effelsberg and the NRAO 43-m telescope at Green Bank, West Virginia. On 22–23 February we observed at 1,666 MHz using the Effelsberg and Green Bank antennae, and also the Jodrell Bank 76-m and Onsala 25-m antennae. Hydrogen maser frequency standards were used at Effelsberg, Onsala and Green Bank, and a rubidium standard at Jodrell Bank. All the cross-correlation of the signals for these experiments was done with the MPIfR processor in Bonn. In the subsequent analysis we attempted to achieve the highest possible sensitivity by integrating the cross-correlation function for as long as the coherence of the local oscillators, atmosphere and ionosphere would allow. This coherence time was determined by observation of the calibration sources 1642+69, BL Lac and 0235+16, which also served to calibrate the gain of the interferometers.

With the resolution used in these observations the double QSO consists only of two compact 'image' components A and B and there is no evidence of any compact structure associated with the extended components seen in lower-resolution maps. The A and B components are characterized by separate residual fringe rates in the cross-correlation function, representing their offsets from a reference 'fringe stopping' position. The long integration times then permit a clear separation of the visibility functions of A and B in the fringe rate spectrum for all but a few periods of time on each baseline (see ref. 10). Data corresponding to these periods were not used in the analysis.

Image structures

The highest sensitivity was obtained at 1,666 MHz. With 10-min integration times, the r.m.s. noise errors on the baselines Effelsberg–Jodrell, Onsala–Effelsberg and Onsala–Jodrell were 3, 6 and 6 mJy, respectively, with minimum lobe spacings in the range 30–60 marc s. On the Effelsberg–Green Bank baseline, which had resolution 6 marc s, the noise level was 5 mJy after 20 min integration. The visibility functions obtained for A and B on these baselines are shown in Fig. 1*a–h*.

The 1,666-MHz data show that A and B exhibit remarkably similar behaviour, both visibility functions indicating structure on the scale of ~50 marc s. The data for the baseline Effelsberg–Jodrell can be compared directly with that reported in Porcas *et al.*[10] which was taken at times corresponding to UT 16–19 h and 0.5 h in our present observations. These are all times which, by chance, were well away from the minima in the visibility functions and we were unable then to attribute the small amplitude differences to source structure.

To derive the source structures from the visibility functions we have fitted simple two-component gaussian models to the 1,666-MHz data. The data from both A and B are fitted well by models consisting of a barely resolved (core) component and an elongated (jet) component. The parameters of the best fitting models are given in Table 1. The visibilities predicted by the model are shown by the solid lines drawn through the data points in Fig. 1. Table 1 also shows errors where the parameter values are well defined by the data. This applies in particular to the position angle (PA) and separation of the jets from the cores in both A and B. Other parameters are less well defined because of strong coupling between their values, for example, the relative flux

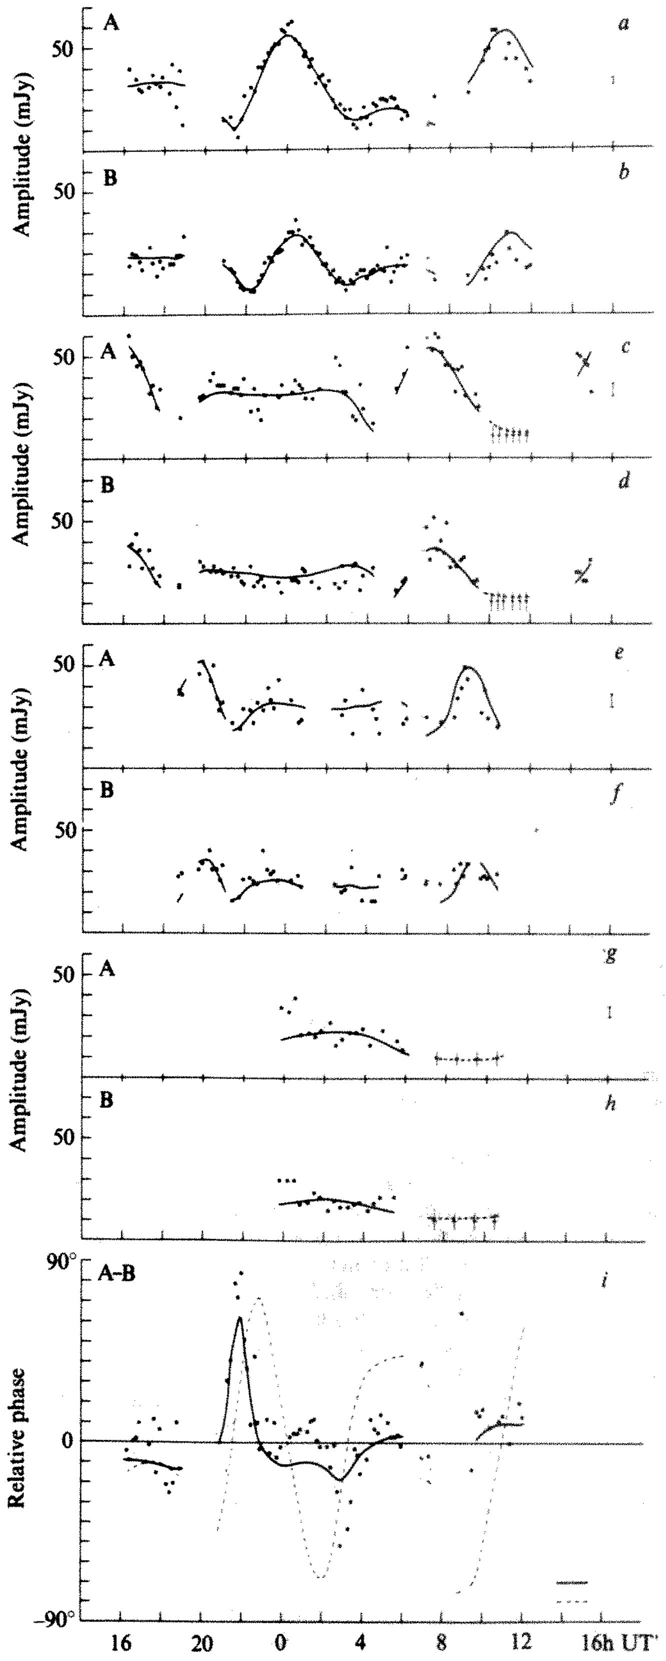

Fig. 1 *a–h*, Amplitudes of the visibility functions of components A and B at 1,666 MHz on the following baselines: *a,b*, Effelsberg–Jodrell Bank; *c,d*, Onsala–Effelsberg; *e,f*, Onsala–Jodrell Bank; *g,h*, Effelsberg–Green Bank. The solid line through the points represents the two-component gaussian models whose parameters are given in Table 1. 1 σ error bars are shown in the top right corners. *i*, Relative phase of the visibility functions (component A–component B) at 1,666 MHz on the baseline Effelsberg–Jodrell Bank. The solid line represents the relative phase predicted from the models fitted to the amplitude data for similarly oriented structures; the broken line is that predicted for opposite orientations. (At 0 h UT, Greenwich ST = 10h 08min.)

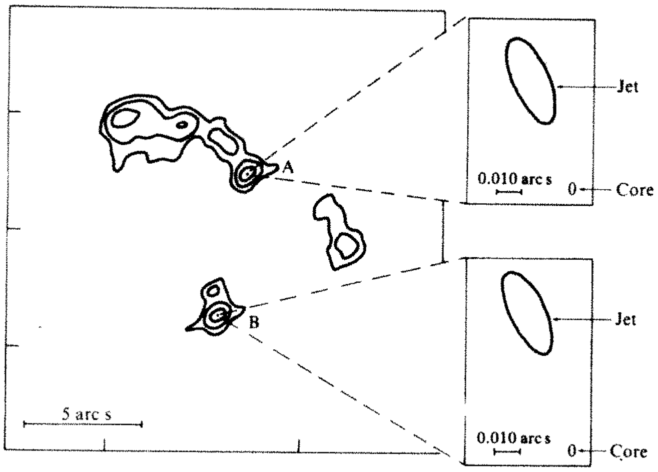

Fig. 2 Outline of the VLBI structures of the images A and B (half-power contour of the fitted gaussian models) projected against the VLA map of Greenfield *et al.*[12].

density between the cores and jets, and their sizes. We have further constrained the flux densities of the jets, however, by requiring that the total model flux density for each component does not exceed the corresponding total flux density derived from low-resolution maps. For this purpose we used the spectra given by Noble and Walsh[13] derived from published flux density values at various frequencies. This procedure seems appropriate as the maximum correlated flux densities we obtained equal these derived values (61 mJy and 43 mJy, respectively).

In general we have only used data from integration periods where we have unambiguously detected both A and B. Occasionally, however, both are undetected, in particular during a 4-h period at the end of the track on the Effelsberg–Green Bank baseline. We have used this information to constrain the models to give low values in these periods and its main effect is to require a slight extension of the core components of ~3 marc s in PA ~−10°. One region where our gaussian model parametrization of the structures is not quite adequate is at the beginning of the Effelsberg–Green Bank track. This indicates the existence of an additional fine-scale structure not represented by these simple core–jet models.

Model fitting to only the amplitudes of the measured visibility functions leads to a 180° ambiguity in the orientations of the structures in both A and B. To resolve this ambiguity we have analysed the relative visibility phase between components A and B on the baseline Effelsberg–Jodrell, which has the highest signal-to-noise ratio (and hence smallest phase noise errors). As the components A and B are separated by only ~6 arc s, measurements of their relative phase are effectively uncorrupted by the various perturbations caused by the atmosphere and the equipment. The relative phase, therefore, represents the true difference between the phase of the visibility functions of A and B. This itself is composed of (1) a sinusoidal function of period 24 h representing the position difference between A and B, and (2) other terms representing any difference in their structure.

We first removed from the measured phase difference a term corresponding to the centroid separation measured by Porcas *et al.*[10]. The correct values are $\Delta RA = -0.1499$ s, Δ dec $= +6.047$ arc s. Due to an algebraic error, the differential precession correction was wrongly applied for the right ascension difference quoted in our previous paper. The corrected values agree well with those quoted by Gorenstein *et al.*[19] from high-sensitivity transatlantic VLBI measurements at 2.3 GHz. The residual phase difference, representing the difference in the structures, is shown in Fig. 1*i*.

In interpreting Fig. 1*i* we consider the following points. If the structures of A and B were identical and oriented in the same sense, the difference phase would be everywhere zero. If A and B had oppositely directed structures then, as the individual structures are themselves asymmetric, the relative phase would reflect this asymmetry, giving values twice that of the phase of either individual visibility function. We assume that the measured centroid separation in fact corresponds to that of the core components in A and B. We would then expect to see these phase departures occurring at hour angles where the jet component (which is 'resolved out' at most hour angles where the projected baseline is not perpendicular to the jet) starts contributing to the correlated flux density.

For the case we have here, the structures of A and B differ anyway, primarily in the separations between the core and jet. Thus, even in the case of the same orientation, we expect imperfect cancellation of the visibility phases where the visibility functions differ most, that is near the minima. This is indeed apparent from Fig. 1*i*, where there are rapid relative phase excursions at UT 22h and 03h. Of particular interest, however, is the return of the relative phase to near zero immediately after the 22h excursion and lasting until the 03h excursion. This is precisely what would be expected for similar orientations as, when both jets contribute to the correlated flux densities, the centroid separation will be similar to that of the cores. (Indeed, this property has enabled us to deduce the correct centroid separation from the consistent phase behaviour away from the minima in our 1979 data.) This is not true for oppositely oriented structures.

This agreement is confirmed by examination of the relative phase predicted from the models of the A and B structures fitted to the amplitude data. The solid curve in Fig. 1*i* is that for similar orientation of structures, with both A and B jets pointing to the north-east; the dashed curve is that for opposite orientations. Although the models do not accurately reproduce the depth of the phase excursion, the gross features of the measured phase difference agree well for the case of the same orientation.

Table 1 Gaussian model parameters

	Separation (marc s)	PA	Flux density (mJy)		Maj. axis (marc s)	Axial ratio	PA
Image A							
Core	–	–	29	61 ± 3	3.5 ± 1.5	0.5 ± 0.1	−10° ± 6°
Jet	46 ± 1	21° + 1°	32		38 ± 3	0.35 ± 0.04	27° ± 3°
Image B							
Core	–	–	24	41 ± 2	2.5 ± 2.7	0.5 ± 0.2	−7° ± 15°
Jet	56 ± 2	17° ± 1°	17		37 ± 6	0.36 ± 0.1	28° ± 3°

A more indirect way of obtaining the component orientations individually uses the 'closure' phase, that is the algebraic sum of three simultaneously measured visibility phases around a closed triangle of baselines[18]. However, to obtain useful closure phase information the data must have a good signal-to-noise ratio on all three baselines for a sufficient period. This was not the case for our data for not only are those from the Onsala baselines very noisy but also there is only one period, from 21.30 to 00.40 UT, where we have reliably separated the contributions from A and B on all three baselines simultaneously. The closure phases for this 3-h period do show features corresponding to the rapid phase changes occurring on the Effelsberg–Jodrell baseline during this time; however, although these are consistent with our deductions from the relative phase, the closure phases do not in themselves provide a reliable independent check on the component orientations.

Our highest-resolution data were obtained from the Effelsberg–Green Bank baseline at 4,996 MHz, with minimum lobe spacing of 2 marc s. With a 20-min integration time we obtained an r.m.s. noise level of 8 mJy, and for much of the track we detected both A and B components at levels of ~28 and ~25 mJy respectively, indicating very compact (≤ 1 marc s) structure in the cores. For the later part of the track, however, both components get weaker and fall below our detection limit. This suggests that the compact core components of A and B are slightly elongated at 4,996 MHz in the same direction as at 1,666 MHz. Haschick *et al.*[14] have obtained very similar data at 5,010 MHz on this baseline, although they attribute the non-detection of A and B at the end of the track to telescope pointing errors.

The agreement of the flux densities detected at the start of the track with the total 5-GHz flux densities of A and B shown by the lower-resolution maps[8,9,11,12] suggests that the jets seen at 1,666 MHz are much weaker at 5 GHz and thus have a steep spectrum.

Interpretation and discussion

The similarity of the structures of A and B clearly confirms that we are seeing two images of a single structure. The core–jet configuration seen in each image is typical of the compact structures of many QSOs and radio galaxies[20]. Figure 2 shows an outline of the model VLBI structures for A and B projected against a map of the larger-scale structure. In the lower-resolution maps at 5 GHz (ref. 12) and 408 MHz (ref. 13) there is an extended bridge of emission between A and the outermost extended structure to the north-east. The jet in the VLBI structure does not point directly at this bridge but it is possible to draw a smooth curve from the core of A through the jet and along the bridge suggesting a continuity between these features. Young *et al.*[4] suggest that the curvature of the complex consisting of A together with the extended structure to the north-east and to the west may be the result of gravitational imaging of a linear structure. The curvature implied by the VLBI structure seems too extreme for this explanation, and the structure of the object itself is probably non-linear. In fact, if component B is excluded, the overall structure is rather similar to that of the QSO 3C309.1 (ref. 21) which is also a triple source showing a marked rotation in position angle between the nucleus and the outer lobes.

The details of the VLBI structure place severe constraints on the mass distribution of the lens. The results of Young *et al.*[3] show that the previously observed properties of the double QSO cannot be produced by a single spherically symmetric mass distribution; such a distribution would require A, B and the galaxy G1 to be co-linear as opposed to the observed skew image line. In their investigation of mass distributions to account for previous observations, Young *et al.*[4] "found it remarkably difficult to fit both the skew in the line and the high brightness of B relative to A. Fitting either one is reasonably easy, but fitting both strained the capacity of the present models".

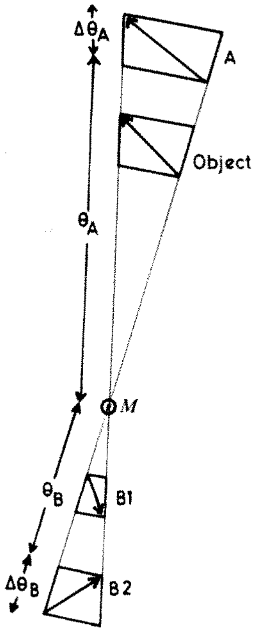

Fig. 3 Schematic representation of the imaging of an object element by a mass distribution, *M*, which has spherical symmetry. The arrows indicate an arbitrary line in the object and the images of this line.

Paradoxically the close similarity between the image structures derived from our VLBI observations is most surprising. To see why this should be so, it is instructive to compare them with those expected with a spherical mass distribution. Bourassa and Kantowski[22] showed that a spheroidal mass distribution will produce one or three images (or, more generally, an odd number). Thus we expect at least one additional image besides A and B. This has been discussed in the context of 0957 + 561 (refs 3, 23) and it is expected that the B image may be split into two separate images. We adopt the notation of Young *et al.*[3] and refer to these as B2 (the outermost image) and B1. Figure 3 illustrates the imaging of an element of the object. We can confidently identify our B image with B2 since the jets in both A and B components point north. Two properties of our model that are quite different from what is produced by a spherical mass distribution are (1) the relative PAs of the core–jet lines, and (2) the relative linear dimensions of the two images.

(1) With a spherical distribution the PAs of the core–jet lines should have opposite signs with respect to the line joining the two images and the galaxy. In our model this is not so; in fact the two lines are almost parallel. Referring to the actual skew galaxy–image configuration[3], the core–jet line of image A has PA +37° with respect to the line A–G1, and the core–jet line of image B has PA +6° with respect to the line B–G1. (We use Stockton's position[5] for G1, that is, 0.19″E and 1.00″N of B.) The fact that the line of structure B points almost directly at G1 must be attributed to chance, because it is determined by the corresponding line of the object which must have a random orientation if the gravitational imaging interpretation is correct.

(2) Because the surface brightness of the images and object must be the same, the flux density ratios of the two images produced by a spherical mass distribution is

$$\frac{S_A}{S_B}=\left|\frac{\theta_A}{\theta_B}\cdot\frac{\Delta\theta_A}{\Delta\theta_B}\right|$$

The ratio of the total flux densities is S_A/S_B is 1.42. (The ratio from our models is 1.9 for the jets and 1.2 for the cores. Though differential amplification is possible along the lengths of the images, these observed values are subject to the uncertain division of flux between core and jet in each component, as pointed out earlier; they cannot be regarded as significantly different.) The observed ratio $|\theta_A/\theta_B|=5$, so the value of $|\Delta\theta_B/\Delta\theta_A|$ from the above formula is 3.5. The best estimate of $|\Delta\theta_B/\Delta\theta_A|$ from our model comes from the core–jet separations and is 1.2 (this is confirmed by the major axes of the jets, for which a value 1.0 is obtained; taking into account the errors, this is not significantly different from 1.2). Thus the length ratio of the two images differs by a factor of 3 from that expected from the simple case of a spherical mass distribution.

It is of interest to put limits on the intensity of image B1. Our visibility functions for B are sensitive to structure on scales up to ~200 marc s. From the lack of any further modulation on our best defined visibility function (Effelsberg–Jodrell Bank) we can put an upper limit of ~5 mJy on the flux density of B1. This rules out Young *et al.*'s[3] model (c) for the system. For separations of B1 from B2 greater than this we become increasingly less sensitive due to smearing of the visibility function by our 10-min integration time, but the VLA map of Greenfield *et al.*[12] already puts strong limits on B1 in this angular range. There is, however, a weak compact feature on the VLA map, coincident with the galaxy G1 within the observational errors, and it has been suggested that this is either the image B1 or emission from G1 itself. This feature is too weak to be detected by our observations, so we cannot say whether it, too, is compact like the A and B components.

Finally, we consider the effect of any intrinsic variations in the radio and optical emission from the quasar. The estimation of the time delay in the variation between images A and B depends on detailed modelling of the lens galaxy and the surrounding cluster[3,4,24]. Variations of the relative intensity in the optical continuum emission have already been reported[4,25] and also in the 5-GHz radio emission[12] and the UV continuum (R. Wilson, personal communication). At frequencies of 1.6 GHz and lower much of the radio emission comes from the steep spectrum jet. Because this is extended and lies $\sim$100 pc away from the core component, we cannot expect this radio emission to vary on time scales as short as a few years. We would thus expect the ratio of the intensities of A and B to vary less at lower frequencies.

Our VLBI measurements of the structures of A and B therefore confirm the interpretation of 0957+561 as a QSO seen through a gravitational lens. The intrinsic radio structure of the QSO has two outer lobes and a compact central component consisting of a jet and a core. We have put limits on the properties of any third image which an extended, transparent lens is expected to produce. The surprisingly close similarity of the orientations of the images and their sizes must be attributed to the non-spherically symmetric elements of the imaging mass distribution.

We thank Professor I. Shapiro for pointing out our differential precession error in ref. 10, and Herr H. Blaschke and Herr Stursberg for operating the MPI VLBI processor. We also thank the staff at NRAO and Onsala for observations. NRAO is operated by Associated Universities Inc. under contract with the NSF. Onsala Space Observatory, Chalmers University of Technology, is operated with financial support from the Swedish NRC.

Halogen and phosphorus storage in the Earth

J. V. Smith

Department of the Geophysical Sciences, University of Chicago, Chicago, Illinois 60637, USA

Speculations on the spatial distribution of elements involve geochemical, geophysical and cosmochemical factors. From analyses of basalts and minerals in peridotites, it is found that: apatite with $\sim$*3 wt% F, and up to 1 wt% Cl and 0.003 wt% Br, is the principal reservoir of halogens in the upper mantle and mica with* $\sim$*0.5 wt% F and 0.05 wt% Cl is a second reservoir; apatite with* $\sim$*18 wt% P accounts for most of the phosphorus in the mantle, but is insignificant with respect to* $\sim$*0.7 wt% P in the core; surface reservoirs contain at least two-thirds to three-quarters of the Cl and Br, but only one-fifth of the F and <1% of the P and finally the Cl and Br contents of the whole Earth are* $<66\times10^{18}$ *and* $<17\times10^{16}$ *kg, using a new estimate of* $\sim10\times10^{19}$ *kg F.*

ALL cosmochemical models for the Earth involve less efficient capture of volatile elements than refractory ones from the solar nebula, but accretion processes[1] are complex. The controversial Ganapathy–Anders[2,3] (GA) model relates elements that would condense nearly together during simple progressive cooling under equilibrium. Chemical analyses of surface reservoirs, coupled with compositions for interior zones inferred from geophysical and geochemical data, were used to obtain a range of estimates of the bulk composition of the Earth[4]. Particularly important are estimates of the extent of transfer of magmatophile elements from mantle to crust by partial melting, and back again by foundering[5–7]. In spite of uncertainties in assignment of elements to reservoirs a general correlation can be implied[2,4,8–12] between volatility in the nebular gas and concentration in the whole Earth. Probable limits on the weight fractions of 14 to 20×10^{-9} U and 14 to 20×10^{-5} K are important.

Table 1 compares estimates of F, P, Cl, K and Br in near-surface reservoirs and whole-Earth models. The last row shows masses assuming that the bulk Earth has the same composition as carbonaceous meteorite of type C1. These masses are multiplied by 1.5 to account for overall depletion of volatile elements in the whole Earth (p. 351 of ref. 4). New analyses[14] of halogens in C1 meteorites are lower than most earlier analyses[13], especially for F, and a revised F/Cl ratio of 0.09 fits electron microprobe analyses of chlorapatites in meteorites (see ref. 15) and other bulk analyses[16,17].

Phosphorus should condense early in the 'metal' fraction of a nebular condensation model[2]. Any uncertainty in the relative fractions of early condensate, silicate and metal components in the Earth is here considered trivial. Phosphorus is strongly bound in minerals of meteorites, and should not be lost to vapour during collisions of planetesimals. If P accretes with the same efficiency as Fe from a solar nebula with C1-type composition, its mass must lie between 10×10^{21} and 14×10^{21} kg, and probably between 11×10^{21} and 13×10^{21} kg.

Potassium and F fall into the volatiles 1,300–600 K group for which the depletion factor with respect to 1.5C1 composition can be estimated from radiogenic elements[5]. If the whole Earth contains between 140 and 200 p.p.m. K, and the revised K/F ratio in C1 meteorite is taken to be 9.1 from Table 1, the content of F should be between 9×10^{19} and 13×10^{19} kg. This gives 10×10^{19} for the GA model.

Cl and Br belong to the volatiles <600 K group. Although many mineralogical details do not fit the theory of equilibrium condensation[18–20], the concentrations of volatile elements in chondritic meteorites[21] fit reasonably well with thermochemical calculations. Although similar depletion factors with respect to cosmic composition were obtained for Tl, Cl, Br and I in the bulk Earth by summation of Earth zones[3], there is an uncertainty in the concentrations of these elements. There is evidence to show that peridotite xenoliths from the mantle were metasomatized by fluids, and the bulk analyses for volatile elements used in

§From ref. 10.

ref. 4 are higher than recent ones for selected xenoliths[22]. Nevertheless, the depletion factors for this group of volatile elements must be assumed to be constant. Ganapathy and Anders[2] modelled the group from an observed Tl/U ratio of 0.27 in terrestrial rocks and an assumed U content of 18 p.p.b. (parts per 10^9) in the whole Earth. Because the measured Tl/U ratio of 7.0 (atomic) for carbonaceous chondrites[23] is close to the value of 7.3 chosen by Cameron[13] for the cosmic composition, and the assumed U content[2] of 18 p.p.b. for the whole Earth is near the middle of the range 14–20 p.p.b. assumed here, the Tl and U content of the GA model needs no adjustment. However, revised estimates of Cl and Br are given.

Potential mineral hosts

Systematic electron microprobe analyses were made of P, F and Cl in minerals from the mantle[24,25]. Halogens were detected only in mica, amphibole and apatite. Amphibole is restricted to the outer 100 km: MARID-suite and secondary-textured crystals in peridotite xenoliths, F 0.5–1.0, Cl 0.00–0.03, K 0.3–4.3 wt%; kaersutite megacrysts in alkali basalts[26], F 0.07–0.22, Cl 0.001–0.012, K 1.0–1.7 wt%. Phlogopite-rich mica is stable down to ~200 km, with the following averages: primary texture in depleted peridotites, F 0.43, Cl 0.08, K 8.6 wt%; secondary textures of various types in peridotites, F 0.63, Cl 0.03, K 8.6 wt%. No large apatite crystals in textural equilibrium with silicate minerals of peridotite xenoliths in kimberlites have been found, but apatites from two lherzolite inclusions in basanites[27] have 0.9 and 1.0 wt% Cl. Apatites[28] from apatite-rich xenoliths in basalts from eastern Australia[29] show 2.1–2.7 wt% F and 0.17–0.22 wt% Cl. A small euhedral crystal enclosed in a dolomite bleb, itself enclosed in a Cr-diopside megacryst found in a kimberlite, contains 0.9 wt% Cl and 1.4 wt% F (ref. 30). A megacryst from the Moses Rock 'kimberlite' contains 0.5 wt% F and <100 p.p.m. Cl (ref. 25). Apatites from seven carbonatites[25] contain high F (2.0–3.7 wt%) and low Cl (0.00–0.1 wt%), and all but one apatite grain from serpentine veinlets in peridotite xenoliths from kimberlites contain low Cl. All apatites contain ~40 wt% P_2O_5, and all silicate minerals contain little P_2O_5, mostly below 0.03 wt% (ref. 24).

Complete incorporation of P into melt was adopted for a model of basalt petrogenesis from melting of mantle pyrolite[31]. A strong correlation between Ce and P in a wide range of basaltic rocks[31,32] can be explained either by the presence of most of the Ce and P in apatite which was totally consumed during melting, or by similar bulk solid–liquid partition coefficients for Ce and P (ref. 32). The good correlation between F and P in oceanic basalts and gabbros suggests that these two elements were present mainly in apatite[25], and rules out the occurrence of whitlockite unless it survived the generation of basalt. Total consumption of apatite is consistent with experiments on apatite saturation in magmas at high pressures[33].

Analyses of F, P, Cl and K in pillow interiors of tholeiitic basalts from the Mid-Atlantic Ridge[34], alkali basalts from the Azores Islands[34] and tholeiitic basalt from the East Scotia Sea back-arc basin[35] were used (Table 2) to determine whether these elements were derived solely from total incorporation of F, Cl-bearing mica and apatite into melt. The atomic ratio (F+Cl)/P for hydroxyl-free apatite is one-third. As all rocks in Table 2 have an average ratio higher than one-third, some halogens must be derived from mica. Table 2*b* shows the amounts of F and Cl needed if K were attributed to mica with the mean composition of the primary-textured type in depleted peridotite xenoliths transported by kimberlites. For the normal mid-ocean ridge basalts and the back-arc-basin basalts, the remaining F and Cl yield (F+Cl)/P ratios close to one-third. For the alkali basalts, the ratio drops to 0.08, which might be explained by: hydroxyl in apatite; lower halogen content of the mica; and derivation of K from halogen-free clinopyroxene[36]. The final option can be ruled out because the K content is too high (12,000 p.p.m.) with respect to the Ca content (~6 wt%). Only the basalts from the Azores transect have a (F+Cl)/P ratio too high to be attributed to hydroxyl-free apatite and primary-type mica, and there are at least three explanations: Cl-metasomatism by seawater; higher halogen content of mica; and precipitation of a mineral with high K/(F+Cl) in a sub-surface magma chamber.

It is assumed here that (1) for tholeiitic basalts from normal ridge segments, assignment of one-fifth of the K to clinopyroxene and four-fifths to primary-type mica would allow the apatite to contain 0.87 atoms of F and 0.13 atoms of Cl; (2) for the back-arc-basin basalts, the apatite contains about 0.67 atoms of F and 0.33 atoms of Cl; and (3) for the alkali basalts, the apatite contains about 0.75 atom of F and 0.25 atom of Cl, while the source mica has ~0.15 wt% F.

Complex processes should be expected however, during transport of a magma to the surface. Tholeiitic basalts at mid-ocean ridges are probably the residue of crystal–liquid processes in near-surface magma chambers[37], and crystallization of apatite and amphibole may cause complications. Apatites from altered gabbros and troctolites from the Mid-Cayman Rise contain 0.15–0.3 wt% Cl (no analysis for F), and most amphiboles contain little Cl (~0.01 wt%) while a few contain substantial amounts (up to 0.9 wt%)[38]. Because F enters crystals in preference to melt, surviving basaltic melt should lose F with respect to parent melt. It will now be assumed that F, Cl-rich apatite and F, Cl-bearing mica are the principal hosts for halogens and phosphorus in the upper mantle. This is consistent both with mass-balance calculations for two lherzolite xenoliths[24] which indicate that silicate minerals provide only about one-tenth of the phosphorus, and with the expectation that H_2O should fractionate preferentially into magma over apatite during crystal–liquid differentiation of the Earth, and the low abundance of primary water in mid-ocean-ridge tholeiitic basalts[39].

Table 2 Interpretation of F, P, Cl and K analyses of pillow interiors of oceanic basalts (*A–C*) and glassy pillow rims of back-arc-basin basalts (*D*)

a Bulk analyses and atomic ratios

D	146	27	106	97	0.217	0.106	0.323

A 20 Mid-Atlantic Ridge tholeiitic basalts from Azores transect (37–40°N).
B 16 Mid-Atlantic Ridge tholeiitic basalts from two normal ridge segments 28–33 and 49–52°N.
C 18 alkali basalts from the Azores Islands.
D 5 back-arc-basin basalts from East Scotia Sea.

Because Cl/Br ratios range only from 222 to 494 for rocks from oceanic ridges and islands[10,40], Br must have the same mineral hosts as Cl.

Tholeiitic basalts from mid-ocean ridges are more abundant that alkali basalts from oceanic islands and the diverse range of magmas in continents, and perhaps give the best clue to the average composition of the upper mantle. Although the compositions of the mineral hosts for halogens and phosphorus cannot be determined, it is suggested that the source regions of basalts contain F, Cl-rich apatite. Values of 3 wt% F and 1 wt% Cl are used for the initial calculations. Because electron microprobe analyses of Cl in apatite from upper-mantle xenoliths range from 0.2 to 1.0 wt% the effect of reducing the Cl content to 0.3 wt% will be considered. For mica, rounded values of 0.5 and 0.05 wt% will be assumed for F and Cl, respectively.

Estimate of P distribution

Subtraction of 18×10^{18} kg F and 37×10^{19} kg K for the crust from whole-Earth estimates in the revised GA model of 10×10^{19} kg F and 10×10^{20} kg K leaves 8×10^{19} kg F and 6×10^{20} kg K for the mantle. Assignment of all K to mica with 8.6 wt% K and 0.5 wt% F would require 35×10^{18} kg F. For apatite with 3 wt% F and 18 wt% P, the remaining 45×10^{18} kg F would require 27×10^{19} P. This is a small fraction of the estimated 13×10^{21} kg P in the whole Earth and hence details of mineral compositions can be ignored. Whitlockite, $Ca_3(PO_4)_2$, was ruled out as a mineral host for P in the upper mantle. The crystal structure of apatite will be assumed to be stable to high pressures. Hence it is proposed that the remaining P goes either into silicate minerals in the deep-mantle or into the core. Because the mass of the entire mantle is 40×10^{23} kg, a mean concentration of 0.3 wt% P would be required for the silicates. Although this is >10 times greater than the concentrations found in olivine, pyroxene and garnet minerals of peridotite xenoliths[24], this possibility should not be ruled out. Experimental syntheses on garnet[43] should be extended to higher pressure. The P could be assigned to the core, for which a concentration of 0.7 wt% would be required. This value lies inside the range for iron meteorites[41] (type I 0.2 wt%; type II 0.12–1.0 wt%; type III 0.07–1.2 wt%), and is consistent with Earth models based on analogy with meteorites. Assigning 0.03 wt% P to the average mantle would lower the estimate of 0.7 wt% in the core to 0.6 wt%. High-pressure reduction of phosphate to phosphide during Earth accretion should also be considered. The inferred content of 0.7 wt% P in the Earth's core is much less than the ~10 wt% S (ref. 42) required to lower the density of the outer core from that for liquid Fe, Ni and there seems to be no geophysical test of the proposed content of P. Proposed contents of C and N in the core[4] are less than for P, but also amount to a substantial fraction of whole-Earth estimates.

Estimate of Cl and Br distribution

Subtraction of the estimate of K in the crust (37×10^{19} kg) from the estimated value for the whole Earth (10×10^{20} kg) leaves 6×10^{20} kg for subcrustal regions. Assigning all this K into primary-textured mica of depleted peridotite would produce 5×10^{18} kg Cl and into secondary-textured mica 2×10^{18} kg. If the mass of F in apatite of the Earth's mantle is 45×10^{18} kg, and the apatite contains 3 wt% F and 1 wt% Cl, the mass of Cl is 15×10^{18} kg. Reduction of the Cl content of apatite to 0.3 wt% drops this mass to 5×10^{18} kg. Hence apatite seems to be a more important store of Cl in the mantle than mica, and especially than amphibole. The estimated mass of $17\text{–}20\times10^{18}$ kg Cl in the mantle (for apatite with 1 wt% Cl) implies that 25–30% of the Earth's chlorine remains in the mantle. The estimated mass of $7\text{–}10\times10^{18}$ kg Cl in the mantle (for apatite with 0.3 wt% Cl) implies that only one-seventh of the Cl remains in the mantle. The $65\text{–}68\times10^{18}$ kg and $55\text{–}58\times10^{18}$ kg are about half of the estimated whole-Earth content of 12×10^{19} kg in the revised GA model.

For Br in the mantle, a Cl/Br ratio of 300, taken from the range of 222–494 in oceanic basalts[10,40], leads to estimates of 6×10^{16} and 3×10^{16} kg Br, depending on the assumed Cl content of apatite. These values are about one-half and one-quarter of the estimate of 11×10^{16} kg in the crust and hydrosphere[10], and imply that about one-quarter to one-third of the Earth's Br remains in the mantle. The $14\text{–}17\times10^{16}$ kg is about one-third of the estimated whole-Earth value of 55×10^{16} kg in the revised GA model.

The above conclusions assume that halogens are absent from the principal minerals of the Earth's mantle. To bring the $65\text{–}68\times10^{18}$ kg Cl up to 12×10^{19} kg Cl in a revised GA model would require $\sim13\times10^{-6}$ weight fraction throughout the entire 40×10^{23} Kg of the mantle; from general crystal-chemical considerations this does not seem plausible.

Conclusions

Within the many uncertainties, I suggest (1) apatite with ~3 wt% F, up to 1 wt% Cl and 0.003 wt% Br is the principal mineral reservoir for halogens, and mica is a subsidiary reservoir; (2) apatite with ~18 wt% P is the principal store of P in the upper mantle and perhaps the lower mantle, but accounts for only one-twentieth of P in the Earth; (3) the remaining P is in a reservoir inaccessible to magmatism, and may amount to a maximum of 0.7 wt% in the core; (4) at least two-thirds to three-quarters of the Cl and Br have entered the crust, but only one-fifth of the F (Table 1) and 0.2% of the P; (5) the whole-Earth contents of halogens, K and P are consistent with less efficient capture of volatile elements than refractory ones from the solar nebula; and (6) the Cl and Br contents should be reduced in the GA model. The distribution of halogens is relevant to crystal–liquid differentiation of the Earth. If all Cl in a subducted slab is returned to the surface by island-arc volcanism[38,44,45], about one-third of the Cl in the mantle has not been transported to the surface, at least since the onset of subduction in the era of plate tectonics. If Cl was returned from the crust to the mantle during the turbulent conditions of the pre-Archaean era[7], it would not be necessary to argue that one-third of the Earth did not melt during accretion. Because present data on phase equilibria indicate that both apatite[33] and hydroxylated silicates[46] are consumed early by partial melting, it would be difficult to justify a model in which halogens could be subducted in preference to K and Rb. Simple two- or three-reservoir models[5,6] for radiogenic elements suggest that the Earth's crust was extracted from only one-half to one-third of the mantle, assuming that the original mantle was chemically uniform (see also ref. 47). This assumption of chemical uniformity may be incorrect, especially for the halogens. It is difficult to see how apatite could have been distributed uniformly throughout the mantle during accretion in view of the large amounts of accretional and core-formation heats. The possibility that apatite in the mantle tended with time to become more refractory by preferential loss of Cl, Br and OH to magma should be considered. Therefore considerable study of geochemical models for the origin and differentiation of the Earth, and further measurements of trace elements in mantle minerals are needed.

I thank A. T. Anderson, R. N. Clayton, J. B. Dawson, J. R. Goldsmith, L. Grossman, R. L. Hervig, G. Reed and especially D. M. Shaw for discussion and review, and I. Baltuska for technical help. Financial support came from grants NSF EAR77-27100 and NASA 14-001-171.

Population dynamics of fox rabies in Europe

Roy M. Anderson[*], Helen C. Jackson[†], Robert M. May[‡] & Anthony M. Smith[*]
[*] Zoology Department and Centre for Environmental Technology, Imperial College, London University, London SW7 2AZ, UK

[‡] Biology Department, Princeton University, Princeton, New Jersey 08450, USA

A simple mathematical model for the overall dynamics of the interaction between fox populations and rabies is presented. The model helps to explain epidemiological patterns observed in Europe, including the 3 to 5 year cycle in fox populations infected with rabies, threshold densities and average levels of prevalence of infection. We give a quantitative discussion of the possibilities of controlling rabies by culling or vaccinating foxes (or by a mixture of the two).

RABIES is a directly transmitted viral infection of the central nervous system, to which all mammals are thought to be susceptible (although not equally so)[1-4]. Throughout human history it has been one of the most feared of all infectious diseases[1,5-9]. Today, the number of people dying from rabies in Europe is insignificant (around 4 per annum in recent years), and even the global total (estimated as high as 15,000 per annum, mainly in India)[10] is dwarfed by other diseases. However, the nature of the clinical symptoms, which are distressing and often hideous, plus the knowledge that death is virtually inevitable once symptoms appear[8,11], makes rabies a continuing cause for concern.

Many major epidemics of rabies have been recorded in Europe over the past seven centuries[1,8], with the dog acting as the main host and primary transmitter of the infection to man. The current epidemic in Central Europe is thought to have originated in Poland in 1939 (ref. 12), and is characterized by a high incidence in the red fox *Vulpes vulpes*; of the 16,820 cases of animal rabies reported in Europe in 1979, over 70% were in this host species[13]. Throughout Europe, and to a lesser extent in Canada and the United States, foxes (red, grey and arctic species) play a dominant role in the transmission and maintenance of the disease, although other mammals (including dogs, skunks, badgers, racoons, wolves and bats) are important in these and other regions of the world[1,7,14-17].

The current European epidemic has spread outwards from Poland at an annual rate of 30–60 km, with the present front in France being less than 40 km from the English Channel coastline (Fig. 1). The introduction of rabies into Britain through illegally imported pets[18] therefore seems a distinct possibility and is especially worrying because of the uniquely high urban and suburban density of foxes, side by side with dense populations of dogs and cats[19,20].

0028-0836/81/090765—07$01.00

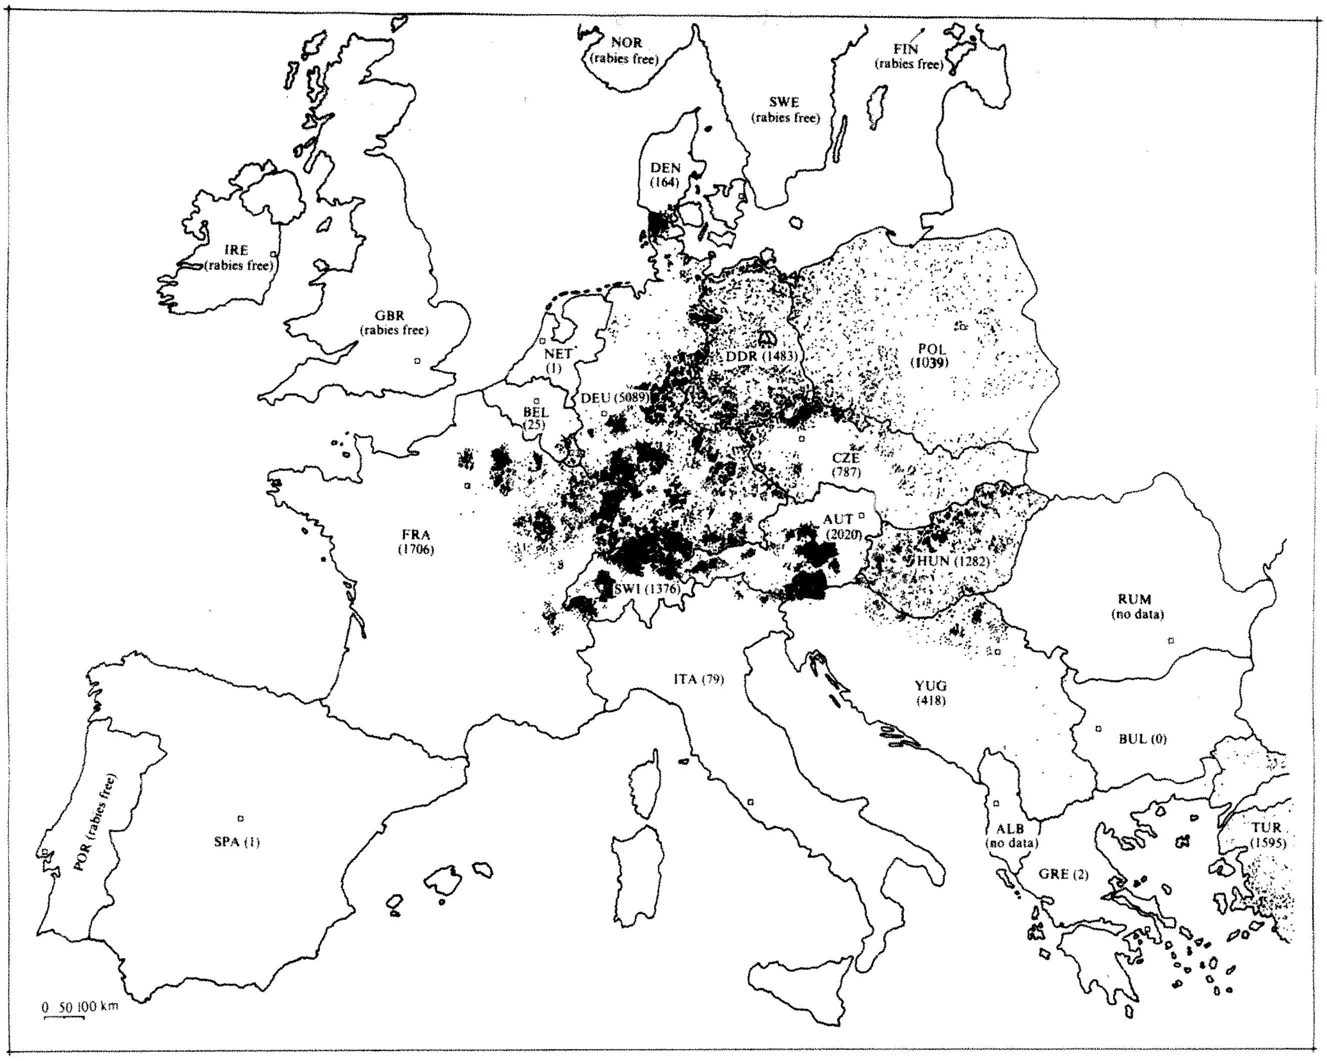

Fig. 1 Geographical distribution of reported European cases of rabies, both in wildlife and domestic animals, during 1979. Each dot denotes one reported case, excepting a few dots in northern Switzerland and southern Germany which represent between one and four cases.

Previous studies of the epidemiology of rabies in fox populations have focused on the characteristics of the viral infection within the host[1,14,21–26], on the ecology of the fox[14,18–20,27–33,101] and on computer simulations along with statistical studies of the spatial and temporal development of epidemics[34–43]. This article, however, takes a different approach in studying the overall population biology of the interaction between foxes and rabies with the emphasis on recurrent epidemic behaviour (in contrast to the more usually studied spatial aspects of rabies epidemiology). We present a simple mathematical model which exhibits patterns of dynamical behaviour in striking agreement with observed epidemiological facts. The model enables us to identify the basic factors controlling persistence of the pathogen, and to assess the effectiveness of different methods for controlling the disease.

Basic model and epidemiological parameters

We use a deterministic, compartmental model in which the fox population is divided into susceptibles, infecteds that are not yet infectious, and infectious individuals; these three classes are defined to have population densities X, I and Y, respectively[44,45]. The model has no category of recovered, immune foxes, because few, if any, foxes recover once the virus is established in the host[1–3,7,8,24,27]. The total density of foxes, N, is thus $N = X + I + Y$.

Foxes are territorial,a family's territory size depending on the type of habitat, food availability and the density of foxes[19,20]. Home ranges in Europe and North America typically lie in the range 2.5 to 16 km^2 (refs 46–52). In the absence of rabies, fox populations seem to increase up to some characteristic density, K, determined by the carrying capacity of the habitat. The value of K is set by the mixture of habitat types in a defined area[19]; within Europe, K is typically in the range 0.1–4 foxes per km^2 (refs 19, 20, 28, 52–54) although much higher densities have been reported in suburban and urban areas of Britain[19,20].

As the death rate of young foxes is density dependent[19,20,28–32], we assume the *per capita* death rate is linearly related to N, such that the net rate is $(b + \gamma N)N$; here, $1/b$ denotes fox life expectancy in the absence of resource limitation, and γ measures the severity of density-dependent constraints. Life expectancy, $1/b$, is typically in the range 1.5–2.7 yr within Europe (Table 1*a*); we take $1/b$ to be 2 yr (Table 1*b*).

Wandeler[55] argues that the rate of reproduction is independant of population density for foxes in Europe, although other reports suggest it may be limited by food availability[30,31,53,54,101]. For simplicity, we assume that density dependence acts primarily on mortality, and that the *per capita* birth rate is a constant, a. The number of cubs in a litter ranges from 1 to 10, with a mean in Europe of 4.7 (refs 14, 18–20, 52, 55). Sex ratios are in general close to unity at birth, and the pregnancy rate is in the region of 90% (refs 19, 20, 55, 56) with a further 10% of vixens failing to produce offspring. By combining these values we obtain for a an average value of 1.0 per annum. The intrinsic *per capita* population growth rate, $r = a - b$, is then $\simeq 0.5$ per annum.

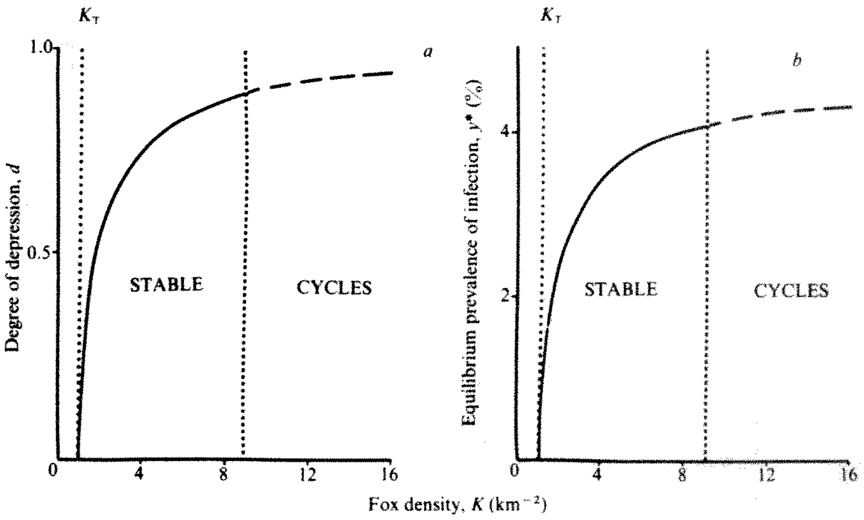

Fig. 2 *a*, Endemic rabies suppresses fox population density to a disease controlled equilibrium N^* where $N^* = K[(\sigma + a)(\alpha + a) - ar]/(\sigma\beta K - ar)$. This steady state density is necessarily less than the disease-free density K, and the degree of population depression induced by rabies, defined as $d = 1 - N^*/K$, is plotted for various values of K. In the region denoted 'stable' the model exhibits damped oscillations to a stable state, and in the region labelled 'cycles' limit cycle behaviour occurs and the dashed line denotes the average degree of depression throughout one cycle. Parameter values again are as listed in Table 1*b*. *b*, This graph portrays the relationship between the equilibrium prevalence of infection y^* and K, where $y^* = (Y^* + I^*)/N^*$, with Y^* and I^* the equilibrium densities of infectious and infected but not yet infectious (latent) foxes. By setting $\mathrm{d}X/\mathrm{d}t = \mathrm{d}I/\mathrm{d}t = \mathrm{d}Y/\mathrm{d}t = 0$ in equations (2)–(4) in the text we obtain $y^* = [(\alpha + \sigma + a - v)/(\sigma + a)][r/(\alpha + a)]D$ where $r = r(1 - N^*/K)$, $D = [1 - 1/R]/[1 - (ar)/[(a + \alpha)(a + \sigma)]]$ and R is as defined in equation (5) of the text. The regions labelled 'stable' and 'cycles' are as defined in the legend to graph *a* and the dashed line in the cycles region denotes the average prevalence of rabies throughout one cycle. Note that both the degree of depression, *d* (graph *a*) and the prevalence y^* (graph *b*) rise as K increases.

These assumptions about the biology of the fox population lead to the familiar logistic equation[57] for the dynamics, in the absence of rabies:

$$\mathrm{d}N/\mathrm{d}t = rN(1 - N/K) \tag{1}$$

Here, the carrying capacity of the habitat at equilibrium is $K = r/\gamma$ (in practice, we try to estimate K itself, rather than γ).

Following conventional lines[58], we assume that the rate at which foxes acquire rabies is proportional to the number of encounters between susceptible and infectious foxes, βXY. Here, β is a transmission coefficient, with $1/\beta$ being proportional to the average time interval between fox contacts; reports suggest that individuals from adjacent family groups meet, on average, every 4 to 6 days[20]. Foxes are assumed to pass from the latent or incubating class to the infectious state at a *per capita* rate σ, such that the average incubation period is $1/\sigma$. This period is variable for foxes (from 12 to 110 days) and depends on factors like age, site of infection and nutritional state[59]; on average, $1/\sigma$ is around 28–30 days[21–24]. Infectious or 'rabid' foxes have a short life expectancy, varying from 3 to 10 days, with an average of 5 days[14,21–25]. We assume rabid animals die at a constant *per capita* rate α; thus, $1/\alpha$ is their life expectancy.

Table 1 Life expectancy ($1/b$) of the red fox and values of epidemiological and other parameters

a	Life expectancy (yr)	Study area
	1.5	Denmark[97]
	1.7	Wales[18]
	1.8	Scotland[28]
	1.9	Suburban London[98]
	2.2	Germany[99]
	2.7	Netherlands[100]

b	Symbol	Meaning	Value
	b	Average *per capita* intrinsic death rate	0.5 yr^{-1}
	a	Average *per capita* birth rate of foxes	1 yr^{-1}
	r	*Per capita* population growth rate, $a - b$	0.5 yr^{-1}
	K	Fox carrying capacity, $K = r/\gamma$	Various
	σ	$1/\sigma$ is the average latent period	13 yr^{-1}
	α	Death rate of 'rabid' foxes	73 yr^{-1}
	β	Transmission coefficient (estimated using equation (7)) for threshold density, $K_T = 1.0$ foxes per km^2	79.69 km^2 yr^{-1}

Because the infection is severely debilatating and of relatively short duration, we assume that infected foxes do not contribute to the reproductive effort of the population.

These biological assumptions lead to the following set of first order differential equations for the dynamics of fox populations infected with rabies:

$$\mathrm{d}X/\mathrm{d}t = rX - \gamma XN - \beta XY \tag{2}$$

$$\mathrm{d}I/\mathrm{d}t = \beta XY - (\sigma + b + \gamma N)I \tag{3}$$

$$\mathrm{d}Y/\mathrm{d}t = \sigma I - (\alpha + b + \gamma N)Y \tag{4}$$

The equation for the total population is obtained by adding the above three:

$$\mathrm{d}N/\mathrm{d}t = aX - (b + \gamma N)N - \alpha Y \tag{5}$$

Table 1*b* summarizes our estimates of the values for the relevant parameters.

Population dynamics

The above formulation differs from conventional epidemiological models[58] in that the host population N is a dynamical variable, affected both by the disease and by density-dependent constraints imposed by resource limitation. Rabies will be maintained within the fox population provided the 'basic reproductive rate', R, of the infection exceeds unity[60,61]; R is the expected number of secondary cases produced during the lifespan of an infectious fox introduced into a population of K susceptible animals. For the system defined by equations (2)–(4),

$$R = \frac{\sigma\beta K}{(\sigma + a)(\alpha + a)} \tag{6}$$

The condition $R > 1$ for endemic maintenance of rabies may equivalently be expressed as the requirement that the fox population exceed a 'threshold density[58,62], $K > K_T$, with the definition

$$K_T = (\sigma + a)(\alpha + a)/\beta\sigma \tag{7}$$

If $R < 1$, or equivalently $K < K_T$, the fox population will settle to its disease-free equilibrium density K.

Epidemiological evidence suggests K_T lies in the range 0.25–1.0 foxes per km^2, with the most frequently reported value in Europe being around 1.0 foxes per km^2 (refs 18, 63–65). This observation can now be combined with equation (7), along with the parameter values listed in Table 1*b*, to give a rough estimate of the transmission parameter β. The value $\beta \approx 80$ yr (per unit density of foxes) thus obtained agrees remarkably well with independently obtained behavioural observations in rabies-free

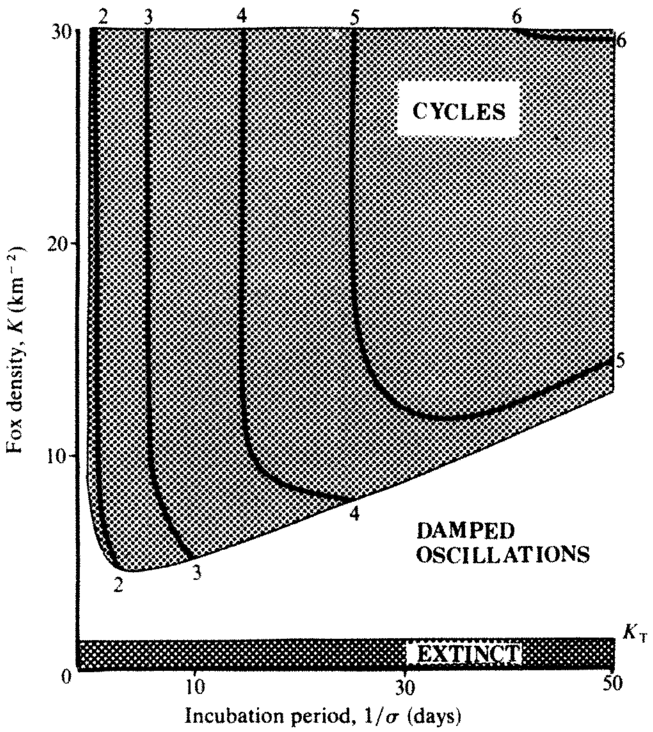

Fig. 3 The three regimes of dynamical behaviour that can be exhibited by the model defined in equations (2) to (4) are illustrated here in the $K - 1/\sigma$ parameter space. As discussed in the text these three regimes are: rabies unable to maintain itself within the fox population ($R < 1$), labelled 'extinct'; fox density controlled to stable equilibrium, N^*, by disease ($R > 1$), labelled 'damped oscillations; and limit cycle behaviour in fox abundance and disease prevalence ($R > 1$), labelled 'cycles'. In this limit cycle region, the contour lines correspond to specific periods of oscillation, labelled in years. All rate parameters are expressed in units of yr^{-1}, and have the values listed in Table 1*b*.

populations concerning the average time interval between fox contacts in regions where the average density is around 1 fox per km^2 (which gives a value for $1/\beta$ of 4 or 5 days, or $\beta \simeq 70$–80^{-1} at this density)[19]. Such agreement seems surprising in view of the belief that rabid foxes have higher contact rates than do healthy animals, although altered host behaviour as a consequence of infection may act to compensate for the fact that only a certain proportion of contacts between healthy and rabid animals will result in disease transmission. When $R > 1$, rabies will regulate fox abundance below the disease-free level K (Fig. 2*a*). This regulated state, however, may be a stable constant value, or it may be a stable cycle; the cyclic solutions tend to arise when the carrying capacity of the fox habitat is relatively large (K significantly larger than K_T).

Figure 3 shows the types of dynamical behaviour which can occur, as functions of the latency interval $1/\sigma$ and the density of the disease-free fox population K, with the other epidemiological parameters having the values listed in Table 1*b*. The values of σ and K discussed above can be seen to suggest cycles with periods in the general range of 3–5 yr. Such periods are precisely what are observed in Europe and North America, where a striking feature of rabies epidemiology is the regular 3-, 4- or 5-yr oscillations in fox density and in the prevalence of infection[6,14,18,24,27,66-69]. The cycles are most commonly observed in regions where fox densities were high before the introduction of rabies, and cyclic behaviour is often absent in low density populations[15]; these tendencies agree with the predictions of the model, as shown in Fig. 3. Qualitative insight into these properties of our model may be obtained by noting that the period of the cycle is determined primarily by the intrinsic growth rate, r, of the fox population (although, as Fig. 3 shows, other factors also influence the period), with rabies acting as a time-delayed density-dependent regulator of fox population growth (the length of the time lag being determined by how long the fox density is below K_T); it is well understood that such mechanisms can induce oscillatory behaviour[70].

For the parameter values most relevant to the epidemiology of rabies in Europe ($1/\sigma \simeq 30$ days, K in the region 1–4 foxes per km^2), Fig. 3 shows the model to predict damped oscillations in fox density and disease prevalence, with periods around 3–4 yr, leading eventually to a stable disease-controlled equilibrium. As illustrated in Fig. 4, however, the damping time is long, being of the order of 40 yr or more from the first appearance of the disease. This propensity to prolonged oscillations, even in the dynamical regime labelled 'damped oscillations' (Fig. 4), is further accentuated by seasonal changes in the values of pertinent parameters. Fox reproduction is clearly seasonal[19,20], and in addition the behavioural ecology of the fox (particularly mating and dispersal patterns) imposes a seasonal trend on disease transmission, which generates a marked peak in disease prevalence from January to April[14,15,24,27]. Numerical studies show that seasonality in the transmission parameter β accentuates the non-seasonal oscillations in prevalence and fox density, considerably lengthening, for example, the damping time in the system portrayed in Fig. 4[71]. In short, the model gives a fairly robust prediction of 3–5-yr cycles in European fox populations infected with rabies[101].

Before leaving the subject of cycles, one further complication deserves mention. In Northern Europe, 4-yr cycles have been reported for rabies-free fox populations; these cycles are likely to be a consequence of the well known 4-yr cycles in populations of microtine rodents in northerly regions[27,28,72-75]. We are, however, not aware of any such cycles in rabies-free fox populations in Central or Southern Europe.

As a direct consequence of its high pathogenicity, rabies will only persist within fox populations at very low levels of prevalence; this is an example of the commonly observed biological relationship between low 'standing crop' and high rate of turnover. Persistence is in part ensured by the high susceptibility of foxes to rabies. In endemic areas of stable rabies, prevalence seems to lie in the range of 3–7% (ref. 76), although significant fluctuations are caused by seasonal effects and by the intrinsically oscillatory nature of the interaction between host and pathogen. As illustrated in Fig. 2*b*, our model gives prevalence values which agree with those observed. Moreover, the model predicts that the prevalence of rabies will be higher in favourable fox habitats (large K), which is consistent with the epidemiological evidence in Germany[14,27,77].

During the troughs in fox abundance (see Fig. 4) the prevalence may drop to very low levels. In these circumstances, the chance of stochastic effects causing extinction of the disease is high, particularly in small areas where the fox habitat is good (and consequently the amplitude of the cycles is large). The persistence of disease over large areas is probably ensured by the high spatial mobility of the fox host; young males may disperse

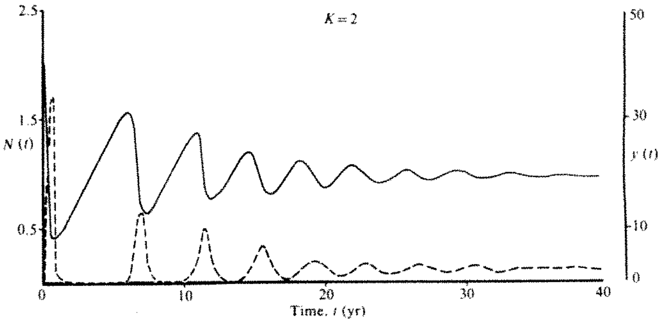

Fig. 4 A numerical solution of the model defined in equations (2) to (4) using the parameter values of Table 1*b*. The carrying capacity of the fox habitat, K, is set at 2 animals per km^2 and $K_T = 1$ fox per km^2. The solid line represents fox density at time t, $N(t)$, and the dashed line the prevalence of infection, $y(t)$.

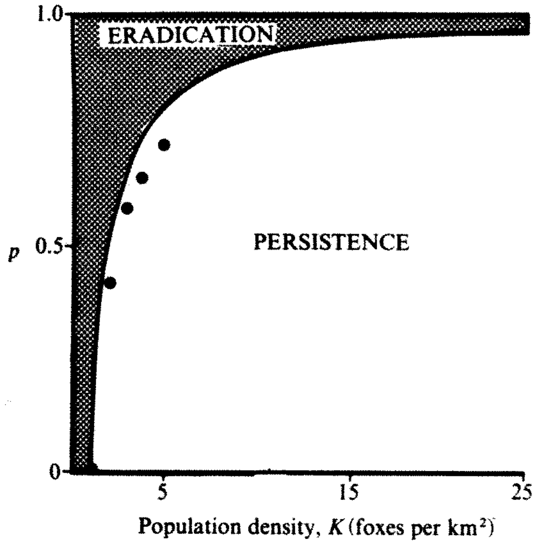

Fig. 5 This figure depicts the relationship between the proportion of the fox population p, protected by vaccination, and the disease-free carrying capacity of the fox habitat K; the threshold density is taken to be $K_T = 1.0$ foxes per km^2. In the shaded region equation (11) in the text is satisfied and rabies cannot persist; in the unshaded region equation (11) is not satisfied and the disease maintains itself. The observation of equation (11) is based on an extension of the model defined in equations (2) to (4) in the text, to include an immune category of foxes of density $2(t)$ at time t; susceptible animals are vaccinated at a *per capita* rate ϕ and immune animals lose immunity at a *per capita* rate δ. The new model is $\mathrm{d}X/\mathrm{d}T = a(X+Z)-(b+\gamma N)X-\beta XY-\phi X+\delta Z$, $\mathrm{d}I/\mathrm{d}t = \beta XY-(\sigma+b+\gamma N)I$, $\mathrm{d}Y/\mathrm{d}t = \sigma I-(\alpha+b+\gamma N)Y$, $\mathrm{d}Z/\mathrm{d}t = \phi X-(\delta+b+\gamma N)Z$. For disease eradication the equilibrium solution (obtained by setting $\mathrm{d}X/\mathrm{d}t = \mathrm{d}I/\mathrm{d}t = \mathrm{d}Y/\mathrm{d}t = \mathrm{d}Z/\mathrm{d}t = 0$) of interest is the disease-free state defined by $Y^* = I^* = 0$ and $N^* = K$. This state is locally stable provided $\phi > (a+\delta)(R-1)$, and the proportion of vaccinated foxes, p, is $p = Z^*/(Z^*+X^*) = \phi/(\phi+\mathrm{a}+\delta)$ which may alternatively be expressed as equation (11) in the text. The four solid circles are the numerical results obtained by Berger[34] from a very detailed model, as discussed more fully in the text. The circles denote the boundary, predicted by Berger's model, between levels of vaccination which result in either disease persistence or eradication.

13 km or more from their birth place, and adult foxes often travel 11–13 km each night[19,20]. Empty territories created by deaths are rapidly occupied by itinerant and mobile male foxes[20]. The involvement of other host species may also be important for the maintenance of endemic rabies during periods when fox abundance is low.

Control by reducing fox density

Attempts to control the spread of rabies in Europe and North America by hunting, gassing, poisoning or trapping foxes have generally met with little success[8,15,19,24,30,76,78]; the disease is still endemic in Poland and West Germany despite intensive efforts to reduce fox density[14,27]. Theory suggests the aim of such programmes should be to maintain fox numbers below the threshold density K_T, given by equation (7). Encouraged by the agreement with observed epidemiological patterns, we now apply our model to explore this problem.

There is a large body of literature, particularly for fisheries and whaling, dealing with the dynamics of natural populations under various regimes of culling or harvesting[79–81]. One approach is to set a constant quota of animals, Λ, to be removed annually in order to keep the fox density at some specified level, below K. In the absence of rabies, the dynamics of the fox population under such culling obeys

$$\mathrm{d}N/\mathrm{d}t = rN(1-N/K)-\Lambda \qquad (8)$$

The analysis of this situation now follows standard lines laid down in the fisheries literature[79–81]. Two cases arise.

If $K_T > \frac{1}{2}K$, the threshold density lies above the point where the fox population growth curve has its maximum (the 'maximum sustainable yield', MSY, point), and stable control to a density below K_T is possible, provided that the culling rate Λ exceeds Λ_T

$$\Lambda_T = rK_T(1-K_T/K) \qquad (9)$$

For K_T in the region of 1 fox per km^2, this regime applies to areas of poor fox habitat, where K is below 2 foxes per km^2; culling can maintain the fox population at a stable equilibrium density $N^* < K_T$.

If $K_T < \frac{1}{2}K$, two complications arise. First, the initial quota must exceed the MSY value, $\Lambda > rK/4$, to drive fox densities below the point (at $\frac{1}{2}K$) where the population growth curve has its peak. Second, the fox population cannot be stably maintained at a finite value below $\frac{1}{2}K$ by culling; the equilibrium point at K_T, attained by culling at the rate Λ_T of equation (9), is unstable. In principle, the population could be driven to extinction by operating at $\Lambda > rK/4$, but in practice a prohibitively large effort would be required to meet this quota when fox density was very low. This regime applies to areas of good fox habitat where $K > 2$ foxes per km^2; such populations will be difficult to control by culling because of the continually high effort needed to keep an area free of foxes, given their ability to disperse over large areas and rapidly to recolonize vacant territories[18,19,82,83].

A different approach is required to devote some specified constant effort (for example, constant number of man-hours) to killing foxes. This regime, in effect, changes the intrinsic *per capita* death rate of foxes from b to $b+\Delta b$, where Δb is the additional mortality imposed by constant effort culling. Fox densities will be maintained below K_T, and rabies eradicated from the population, provided

$$\Delta b/r > 1-1/R \qquad (10)$$

Here, R is the 'basic reproductive rate' for rabies in the original population, as defined in equation (6). Again, we see that if R is large, as it typically is in good fox habitat, Δb must essentially equal r itself, which implies a considerable level of effort. The practical implications of these predictions need to be assessed particularly with respect to the relationship between effort (determined by r and K), fox density and the rate of mortality achieved by control measures.

Other, more elaborate, culling regimes could be considered, but the broad theoretical conclusion remains that the control of rabies by culling foxes will be difficult to achieve in all except poor habitats, and even in these continual effort must be applied. Such conclusions agree with recent experience in Europe, and are a consequence of the high reproductive potential and dispersal behaviours of foxes[18,20,82,83].

The use of pathogens such as canine distemper or canine hepatitis as suppressors of fox numbers may be a feasible alternative, provided the threshold density for maintenance of the introduced pathogen is lower than that for rabies. Field observations in North America suggest that a more detailed appraisal of this approach is warranted[66].

Control by vaccination

The possibilities of immunizing wild foxes against rabies have been vigorously pursued in recent years[84–87], even though many problems surround this approach (not the least being the danger than an attenuated live vaccine which effectively immunized foxes might introduce a mild form of the disease into other host species)[1,19,88]. Substantial progress has been made, however, in the development of oral vaccines and in techniques for delivering them in baits[88–90]. Extensive field trials have been carried out, for example, in Canada, Germany and Switzerland[19,89,91,92]. In the design of these trials, there has been much discussion about the level of protection needed within the fox population to eliminate rabies[19,34,36,43].

Our model provides an answer: the proportion of the population, p, that must be protected at any one time is simply

$$p > 1 - 1/R \qquad (11)$$

Here, R is as defined in equation (6) (see also Fig. 5 legend)[60,61,71]. This general relation (11) is illustrated in Fig. 5. Because R may equivalently be written as $R = K/K_T$, we see that K_T is the only parameter involved in specifying p as a function of K.

Figure 5 also displays the results of an elaborate numerical simulation by Berger[34]. His model involves a detailed statistical description of dispersal by, and contact between, foxes on a large two-dimensional grid, along with statistical distributions for the duration of latent and infectious states in individual foxes. Like us, Berger took K_T to be 1 fox per km^2, and there is good agreement between the results of this detailed study and the simple equation (11); Fig. 5 provides a good example of the basic understanding that can be gained from simple models.

Equation (11) and Fig. 5 show clearly that the required degree of protection is greater in dense fox populations than in sparse ones; for K around 2 foxes per km^2, roughly 50% of the population must be protected (given the K_T of Table 1*b*). Vaccination thus seems to be a better method than culling, particularly in view of the 74% level of protection achieved by Johnston in Canada[19,93] and the 60–70% bait acceptance attained in Germany[89]. In good fox habitats, however, the required protection level approaches 100% (see Fig. 5), and will be difficult to achieve.

Control by vaccination and culling

If vaccination (of a proportion p of the fox population) is combined with constant effort culling (which adds Δb to the fox death rate), the criterion for eradication of rabies becomes

$$p + q - pq > 1 - 1/R \qquad (12)$$

Here, $q = \Delta b/r$. This criterion generalizes equations (10) and (11), to provide an explicit estimate of the efficacy of a combined strategy. For instance, if $R = 4$ we would need to vaccinate 75% of the foxes, or to kill at a rate $\Delta b/r = 75\%$, under a pure strategy; a combined strategy would require, for example, $p = 50\%$ and $\Delta b/r = 50\%$. Without making any estimate of the relative costs, it does seem likely that the expenses of vaccination or of culling will rise faster than linearly with increasing p or Δb, so that the combined strategy may often be the most cost effective (as well as permitting more foxes to live than does pure culling).

Conclusion

In the event of an outbreak of rabies among wildlife in Britain, the government's official policy is to concentrate on the destruction of foxes[18,19,94]. Our theoretical results, analysed in the light of available data, support MacDonald's conclusion[19] that such an approach is unlikely to be effective once rabies becomes established within the fox population[83,92,95]. Vaccination, conditional on the development of a 'safe' vaccine[96], and supported by culling in low density fox populations, is more likely to be successful. Our model provides a quantitative framework for discussing the precise level of control (whether vaccination, or culling, or a mixture) required in different fox habitats.

In view of the predicted difficulties of controlling rabies within areas of good fox habitat, the most sensible priority would be the compulsory vaccination of dogs and cats, along with eradication of strays and feral populations, so as to minimize the risk of human exposure in urban and suburban regions of Britain.

When assessing the significance of these conclusions it is clearly important to bear in mind the limitations of simple deterministic models (based on assumptions of homogeneous mixing), which ignore spatial and stochastic effects, and the accuracy of the data base used for parameter estimation. The power of simple formulations lies in the relative ease with which relationships can be established between important variables, a facility rarely provided for by complex simulation models (see equation (12) and Fig. 5). We emphasize, however, that our model predicts patterns of population behaviour in striking agreement with observed epidemiological trends. This leads us to believe that, by the specification of a few easily measured parameters, the model captures the significant features of the population association between host and pathogen and is thus of practical value to the design and implementation of control measures. To improve the accuracy of model predictions, however, additional data are ideally required, particularly with respect to the threshold density, K_T, the demography of fox populations in Britain and the dispersal behaviour plus contact rates of rabid foxes.

The molecular structure and stability of the eye lens: X-ray analysis of γ-crystallin II

Tom Blundell, Peter Lindley, Linda Miller, David Moss, Christine Slingsby, Ian Tickle, Bill Turnell & Graeme Wistow

Laboratory of Molecular Biology, Department of Crystallography, Birkbeck College, University of London, London WC1E 7HX, UK

The three-dimensional structure of the eye lens protein, bovine γ-crystallin II, has been determined at 2.6 Å resolution. The protein has a two domain β-structure, folded into four remarkably similar 'Greek key' motifs, and shows the highest internal symmetry of any protein studied by X-ray analysis. Although the symmetrical structure seems very stable, the arrangement of the sulphydryl groups would allow intramolecular cross-linking leading to possible destabilization, and intermolecular cross-linking leading to aggregation, both of which may be important in cataract formation.

ALTHOUGH eye lenses have evolved to suit the requirements of many ecological niches—from the very hard lens of the short-sighted rat to the very soft lens of birds capable of wide-ranging accommodation—all vertebrate lenses have a similar cellular structure comprising long fibre cells which pack hexagonally in spherical laminae. These grow throughout life, differentiating from the surface epithelial cells and overlaying older cells, so that the core of the adult lens is formed from the original fetal structure.

The transparency and refractive power of the normal lens depends on a smooth gradient of refractive index for visible light. This is achieved not only by the regular arrangement of the fibre cells, but also by a smoothly changing concentration gradient of lens-specific proteins, the crystallins, and other cell components.

The largest of the soluble crystallins, α-crystallin, is an oligomeric globular protein of molecular weight (MW) $\sim$800,000. There are two gene-product subunits, αA_2 and αB_2, both of MW[1,2,3] 20,000. A proportion of these undergo post-translational modification[4], which contributes to the considerable heterogeneity and polymerization of native α-crystallin[5,6]. β-Crystallins are also a heterogeneous class of proteins which exist as oligomers of several different sizes[7,8]; the subunits vary in MW between 20,000 and 32,000 with the predominant species, βBp, of MW 26,000 (ref. 9). γ-Crystallins, however, are monomers of 20,000 MW[10], with highly homologous sequences[11,12]. They show no similarity to α-crystallin, but a striking homology to the sequence of βBp-crystallin has been recently observed[13]. γ-Crystallin II, the major species in the bovine lens, has six free sulphydryl residues[11].

Little is known of the conformation and intermolecular interactions of the crystallins which give rise to the supramolecular organization within the fibre cells. However, it is established that the increased light scattering of senile nuclear cataracts is associated with protein aggregation[14–16], together with chemical cross-linking, including disulphide bridges[17–20] and denaturation[21].

Here we report the three-dimensional structure of bovine γ-crystallin II at 2.6 Å resolution—the first X-ray analysis of a lens protein. The protein has a two-domain β-structure, folded

Table 1 Phasing statistics for the five heavy-atom derivatives given in resolution ranges

Reagent	Uranyl acetate	Thiomersal		Potassium auricyanide		Ethyl mercury chloride	Sodium hexachloroiridate (IV)	
Resolution	16→4.5 Å	16→3.4 Å	3.4→2.6 Å	16→3.4 Å	3.4→2.6 Å	16→3.4 Å	16→3.3 Å	3.3→2.8 Å
$\bar{F}_{PH}$	323.7	321.1	209.4	318.8	208.5	296.8	313.9	220.2
$\bar{F}_H$	35.7	64.9	44.3	51.7	41.9	100.1	54.4	40.2
E_H	40.9	37.2	35.0	39.5	37.4	66.6	60.1	43.0

$\bar{F}_{PH}$, mean value for the derivative protein structure factor amplitude. $\bar{F}_H$, mean value of the contribution of the heavy atom to the structure factor of the derivative. E_H, r.m.s. lack of closure[27] for the heavy-atom derivative.

Fig. 1 The sequence of γ-crystallin II. The numbering is that of Croft[11] and subscripts indicate insertions or replacements necessitated by the electron density map. These generally improve the homology with the sequence of βBp-crystallin reported by De Jong *et al.*[13]. The sequence is divided into four major, approximately equal parts which correspond to the four Greek key motifs, each with four strands: a, b, c and d. Topologically equivalent residues are in columns and the secondary structure indicated by the torsion angles is given: β, β-sheet; R, right-handed helix generally distorted from α-helix; L, left-handed helix, and G, a conformation found usually with glycine, with $\phi \sim 110°$ and $\psi \sim -110°$. The connecting peptide links the two domains.

into four remarkably similar Greek key motifs[22]; it shows the highest internal symmetry of any protein studied by X-ray analysis. Each domain comprises a sandwich of two four-stranded sheets, each sheet being made from three strands of one 'Greek key' motif and one strand from another. The sequence shows a functional conservation of a few important residues in each of these motifs which had not been recognised earlier. This repeating structure, which may have evolved through gene multiplication, could be of general significance to other lens proteins in view of the sequence homology with βBp-crystallin[13]. Although the symmetrical structure has the appearance of great stability, the sulphydryl groups are arranged in ways which could allow both intramolecular and intermolecular cross-linking, and reaction with certain sulphydryls could be expected to destabilize the conformation and lead to denaturation. The arrangement of charged and non-polar groups on the molecular surface has implications for the stability of the molecule, the nature of the hydration around lens proteins and the intermolecular contacts which may be important to the supramolecular organization of crystallins in the normal lens.

X-ray analysis

The γ-crystallins were isolated from calf lens using gel filtration on G-75 Sephadex to separate the α- and β-crystallins[23], ion-exchange chromatography on DEAE-Sephadex to separate the βs-crystallin (MW 28,000)[24], and ion-exchange chromatography on sulphopropyl-Sephadex and DEAE-cellulose to separate the γ-crystallins I, II, III and IV (refs 25, 26). Large crystals of γ-crystallin II were grown from 0.05M phosphate buffer, 1mM dithiothreitol, *p*H 7, at 0 °C (ref. 26). The crystals were stabilized by cross-linking overnight in 3% glutaraldehyde in 0.05M sodium phosphate buffer, *p*H 7. Four heavy-atom derivatives were prepared using uranyl acetate, thiomersal, potassium auricyanide and ethyl mercury chloride as described elsewhere[27] and a further derivative using sodium hexachloroiridate (IV). Data were collected on a Hilger-Watts four-circle diffractometer with Ni-filtered CuK$_\alpha$ radiation to the resolutions indicated in Table 1. Typically, ω scans with 1° scan width and 50-s counting time including background were analysed using a moving-window technique[28] to obtain the net integrated intensity. Two equivalents (hk*l* and kh*l*) for the native and four equivalents (hk*l*, kh*l*, hk$\bar{l}$, kh$\bar{l}$) for the derivatives were measured so that two estimates of the anomalous difference of each reflection for the derivatives were obtained. Empirical absorption corrections were applied using a modification of the method of North *et al.*[29] and radiation decay was monitored by standard reflections measured every hour. The heavy-atom positions were determined using F_{HLE} Patterson syntheses and refinement (see ref. 30 for review) and the relative hands and origins of the individual derivatives, and the absolute hand of the model, were established using cross-phase difference Fourier syntheses incorporating the anomalous differences[27]. Phases were calculated using the method of Blow and Crick[31] and the phasing statistics are summarized in Table 1. The mean figure of merit was 0.89 at 5.5 Å resolution but fell to 0.70 in the range 3.0–2.6Å resolution.

A 'mini' electron density map at 3.4 Å resolution was calculated at a scale of 1 cm = 3Å and the path of the polypeptide was followed. The 2.6 Å electron density map was initially interpreted using an optical comparitor[32] (scale 1.25 cm = 1 Å) and the α- and β-carbon, carbonyl oxygen and some side-chain positions of this model were recorded. These were then displayed on an Evans and Sutherland Picture System II using FRODO[33] modified and extended by A. Jones and I. J. Tickle. The backbone atoms were generated using the input coordinates as guide points, with the model-building routine of Hermans[34], in the FRODO program and the coordinates improved interactively using computer graphics. The addition of side chains presented problems as some modifications to the sequence published by Croft[11] were required mainly in the hydrophobic regions. Our sequence (Fig. 1) is an attempt to fit the observed electron density but at the same time to minimize the number of implied errors in tryptic and cyanogen bromide peptide sequences which were used to derive the primary structure. The new sequence has higher homology to the sequence of βBp (ref. 13) and also higher internal homology (*vide infra*) than that published previously[11]. The numbering scheme uses alphabetical postscripts where the residues differ from the Croft sequence.

The topology of the folding units was compared using EZIFIT of A. D. McLachlan[35]. Thirty-six topologically equivalent residues were compared, including all residues shown in Fig. 1, and equivalent to residues 1–37 with the exception of residue 21. This program optimizes the fit without assuming a strict 2-fold rotational symmetry. A program written independently by W.G.T. was used to find the agreement to a rotation of 180°. The motifs were also compared using interactive computer graphics to optimize their overlap, using a program FITZ written by Dr G. Taylor of our laboratory.

Symmetry and stability

The low-resolution electron density map[27] showed that the γ-crystallin molecule is ellipsoidal and organized into two well defined globular domains. It can now be seen that the N-terminal half of the sequence comprizes one domain and the C-terminal half the second; the overall topology of the two domains is strikingly similar. Each domain is organized into two folding units (see Figs 2–4) that adopt a structure resembling a 'Greek key' motif[22] shown schematically in Fig. 3*b*. We have divided the sequence into four sections of about 40 residues, labelled I–IV in Fig. 1, so that I and II correspond to the Greek key motifs in the N-terminal domain and III and IV correspond to the motifs of the C-terminal domain. There is a short connecting peptide between the two domains, which are related by an approximate diad axis so that 80 α-carbon atoms of the N-terminal domain (38 of motif I and 42 of motif II) are topologically equivalent to those of the C-terminal domain with root mean square (r.m.s.) distance at best fit of 1.42 Å as calculated using EZIFIT[35] (rotation angle, 178.1°; screw shift, 0.14 Å).

We compared 36 common, topologically equivalent α-carbon atoms of each motif. For motifs I and II related by an approximate diad within the N-terminal domain, the r.m.s. distance was 2.40 Å (rotation angle, 179.3°; screw shift, 1.32 Å). Motifs III and IV in the C-terminal domain similarly gave a r.m.s. distance of 2.76 Å (rotation angle, 179.8°; screw shift, 1.12 Å). However, the most striking relationship is between motifs II and IV, where 42 consecutive α-carbon atoms in the two motifs are related with a r.m.s. distance of 1.05 Å, and between motifs I and III where 36 topologically equivalent residues are related with a r.m.s. distance of 1.74 Å.

The diad relating atoms of the two domains bisects the angle of ~40° between the diads relating folding units, all three diads being approximately coplanar. These observations demonstrate that folding units I and III are similar, as are II and IV. There is a less close correspondence between the folding units within one domain—this is illustrated in Fig. 2 which compares the α-carbons of the folding units.

Given the similarities between the Greek key motifs it is convenient to first describe motif I and then to relate the others to this. The sequence in Fig. 1 has been arranged so that topologically equivalent residues in each motif occur in one column, and an indication of the conformation of residues is included so that secondary structures can be inferred.

Each 'Greek key' comprises four antiparallel strands. In motif I (Fig. 3*a*), residues 2–6 (strand a) form an extended chain in β-sheet conformation that runs antiparallel and is hydrogen-bonded to residues 14–18 (strand b). The turn between residues 7 and 13 is made possible by Glu 7 assuming a right-handed helical conformation and Gly 13 having the ϕ, ψ values of 126° and −116°, respectively, which are normally disallowed for residues with side chains. Residues 10 and 11 assume the conformation of a left-handed α-helix so that the side chain of

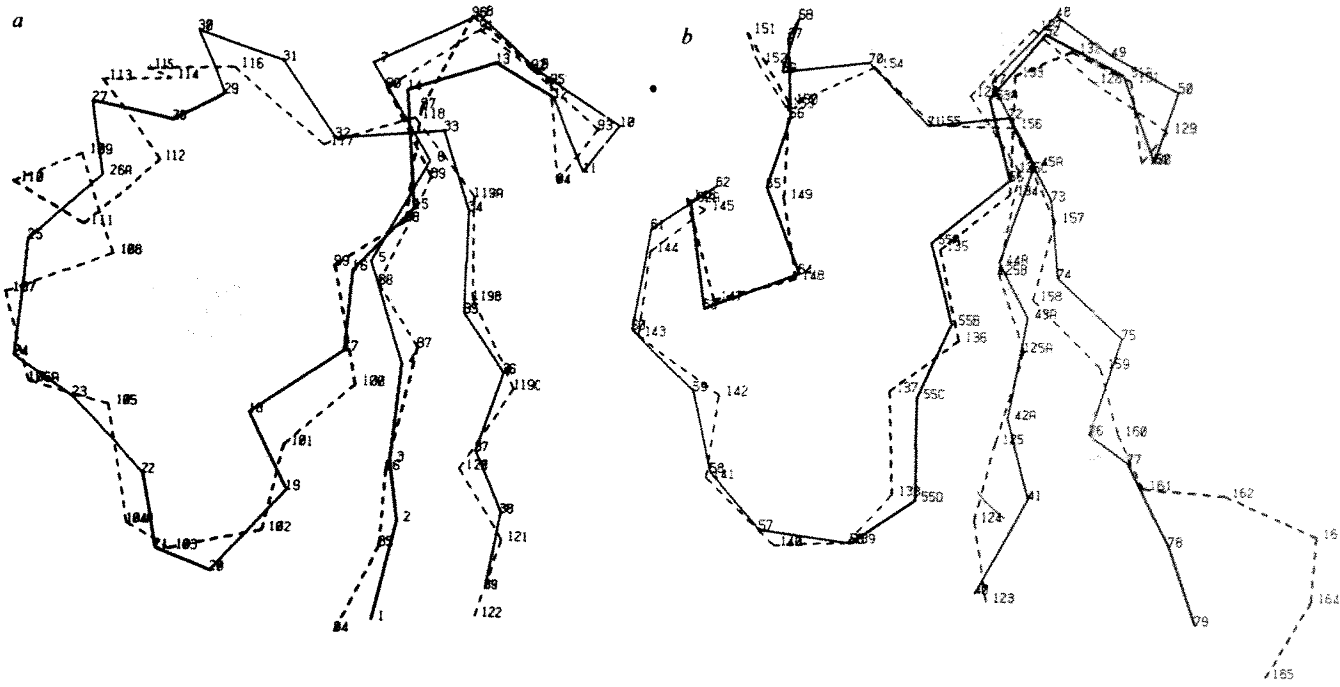

Fig. 2 The path of the polypeptide chain is illustrated by the positions of the α-carbon atoms for each of the folding motifs defined in Fig. 1. *a* Shows the best fit of motifs I and III obtained visually using interactive computer graphics (program FITZ of Dr G. Taylor). *b*, A similar best fit from an equivalent direction for motifs II and IV, which show the closest resemblance in sequences between the topologically equivalent residues.

Phe 11 is packed on to the antiparallel sheet against Tyr 6. The structure of residues 1–18 may therefore be described as a two-stranded antiparallel β-pleated sheet which has a turn at residues 10 and 11 and which is folded at residues 7 and 13.

Residues 19–21 form a further turn so that residues 22 and 23 lie antiparallel and adjacent to residues of strand b. After residues 22 and 23, which have a β-sheet conformation, the chain assumes a rather irregular, right-handed helical structure between residues 24 and 28. The following residues form a gentle bend so that residues 32–38 form strand d, which is hydrogen-bonded as part of the antiparallel β-sheet including strands a and b.

Figures 2–4 indicate that the conformations of motifs II, III and IV may be derived from that of motif I by insertions and small changes in conformation. The major differences between motifs I and III are the deletion of one residue in the turn between strands b and c and the insertion of three residues as a continuation of the right-handed helical region at the end of strand c. Motifs II and IV are slightly larger than I, with four insertions in the loop between the helical region at the end of strand c and strand d. Figure 4 shows that the hydrogen bonding in the β-sheets is similar.

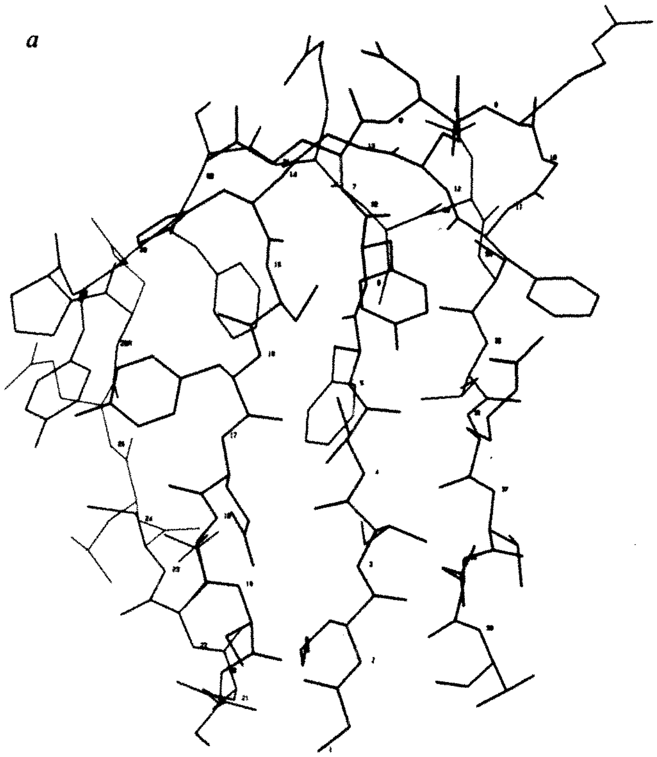
The Greek key motifs pack together so that each domain comprises two right-handed, twisted, antiparallel β-sheets sandwiched together (Fig. 3*c*). The fourth strand of each sheet is comprised of strand c of the other motif in the same domain as indicated in Fig. 4. As strand c is of a less regular β-sheet structure than the other strands, it makes few well defined hydrogen bonds. The angle between the planes of the β-sheets is ~35° giving the domains the wedge shape seen in Fig. 3*c*, and the angle between individual strands in opposing sheets projected on to the mean plane is ~20°. The volume between the β-sheets is occupied by hydrophobic side chains; these are more predominantly aromatic near the top of the wedge. The top of the wedge-shaped domain is enclosed by the two antiparallel strands c and d of the two Greek key motifs. In motif I the following residues contribute to the core: 3, 5, 16, 18, 23, 28, 32, 35, 37; the topologically equivalent residues in Fig. 1 (columns beneath the residues listed) also contribute to the cores of the domains, making them compact and largely hydrophobic. Residues in strands b and c have their hydrophilic functional groups folded in such a way as to minimize the contact of the core with the solvent.

The two domains are packed together (Fig. 5) so that the two sheets involving strands a, b and d of motifs II and IV are sandwiched with an angle of 20° between the individual strands. The contacts are again largely hydrophobic and include Phe 43A and Met 55B of the N-terminal domain, and Val 125A and Leu 136 of the C-terminal lobe. The connecting peptide is accommodated so that it follows the surface of the molecule.

The structure of γ-crystallin shows the highest degree of intrachain symmetry of any protein whose three-dimensional structure has been elucidated. The eye lens proteins must exist throughout the life of the animal without denaturation, due to the fact that to avoid sharp changes in refractive index which would result from irregular structures, the fibre cells become denucleated and have few cellular organelles such as mitochondria and ribosomes. As there is little or no capacity for regeneration, the proteins must be relatively stable, and we suggest that the high degree of symmetry of these proteins may contribute towards this stability.

Gene multiplication in evolution?

The similarity in the three-dimensional structure of the motifs poses the question as to whether the structure may have evolved divergently in two stages: first, gene duplication and fusion of a protein of ~40 amino acid residues to a protein approximating the present γ-crystallin domain, followed by a further gene duplication to give the two-domain structure. This model is consistent with the observation that the two domains resemble each other more closely than do the two motifs within each domain. This is also evident from the sequence homologies



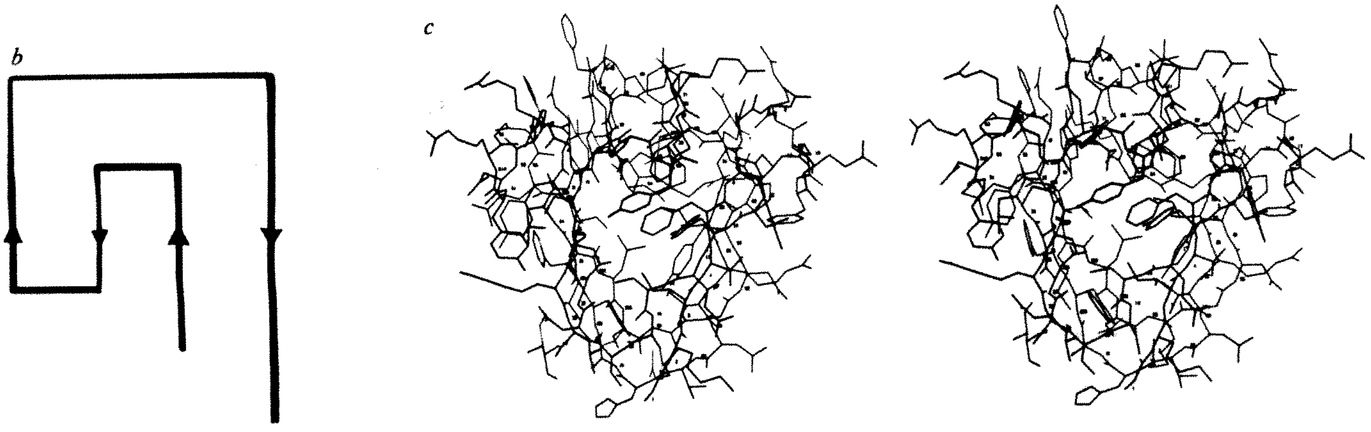


Fig. 3 *a*, The arrangement of the amino acid residues in a Greek key folding motif viewed at about right angles to the plane formed by strands a, b and d, which are defined in Fig. 1. *b*, The Greek key motif shown schematically. *c*, Stereo diagram of the N-terminal domain showing the wedge-shaped packing of the two motifs.

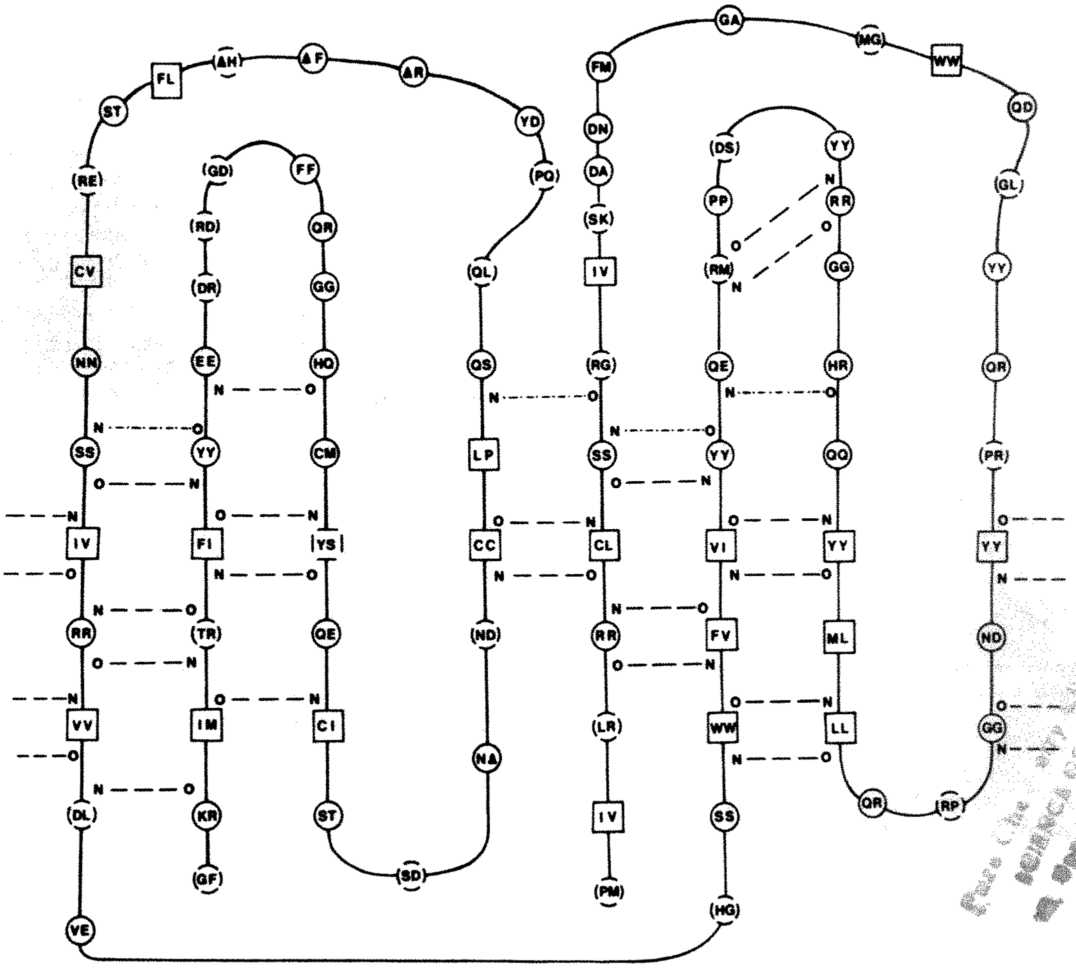

Fig. 4 The arrangement of the amino acids in a γ-crystallin domain shown schematically. Each box indicates the nature of the two topologically equivalent amino acids of the two domains. Deletions in one domain are given by ▲. Square boxes indicate residues which are directed either between the sheets within the domains or between the sheets between the domains; some of these residues in strands b and c (see Fig. 1 for definition) are on the edge of the sheets and are therefore partially accessible to solvent. The extent of the sheets is indicated by the length of strands shown in Fig. 1 and also by the hydrogen-bonding network. Those hydrogen bonds common between the two domains are indicated by ----- whereas those occurring in one domain only are indicated by -·-·-.

illustrated in Figs 1 and 4, which must, however, be read with caution as they involve inferences from the electron density map. The number of residues conserved at topologically equivalent positions between motifs is much greater for motifs II and IV than for the two motifs within either domain. These observations are consistent with the model for two sequential tandem duplications.

Only four residues are invariant at topologically equivalent positions between all folding units. These include Tyr 6 which has a structural role in packing against the conservatively varied Phe 11 (Tyr) of the folded β-turn between strands a and b (Fig. 6) and Gly 13 which has angles disallowed for other residues and allows the fold to occur. Glu 7, which is necessary for the folding

over of the β-structure, is very conservatively varied to Gln (in motif III alone). The third invariant residue, Ser 34, is also involved in this structure (see Fig. 6). The γ-O of this serine in each folding unit is relatively shielded from solvent and hydrogen bonds to the peptide nitrogen of the residue topologically equivalent to Phe 11 on the turn. This most unusual structural motif is further stabilized by the fourth invariant residue Arg 36, also shown in Fig. 6; this arginine seems to be well ordered and to have its aliphatic side chain against the aromatic ring of Phe 11 with its guanidinium group exposed to the solvent. The fact that this arrangement is strongly conserved both in three dimensions and in sequence underlines the importance of these amino acids, but their structural role would be consistent with convergent evolution as well as gene multiplication and divergent evolution.

One of the surprising aspects of the structure is that very few residues of the hydrophobic core are invariant. It seems that there are several ways in which the same volume occupation of side chains of the core can be achieved while still allowing a very close three-dimensional homology. Evolution–whether convergent or divergent–seems to have exploited these possibilities and it is this variation, combined with the insertions and deletions in the bends, which makes recognition of structural homology very difficult from sequence alone. If this is divergent evolution, here is further evidence that three-dimensional structure is more strongly conserved than sequence.

Surface characteristics

The surface of the γ-crystallin II molecule is characterized by a number of extremely well defined charged and polar side chains, many of which seem to be organized in pairs or chains of ionic and/or polar interactions. For example, Glu 7 and Asp 8 at the beginning of the fold between strands a and b of motif I have their acidic side chains lying on either side of the basic guanidinium moeity of Arg 31 at the beginning of strand d; Glu 116 is bracketed by Asn 118 and Asn 152; Glu 122, Arg 85, Glu 100 and Arg 87 form a chain of ionic interactions.

The most extensive network of charged groups is centred on Asp 92 and includes a series of six alternately positively and negatively charged side chains in one molecule (Fig. 7). However, one end of the chain, Arg 144, is close to Asp 103 of a symmetry-related molecule at a crystal lattice contact point so that the ionic interactions connect neighbouring molecules. In fact, Glu 90 and Arg 91, adjacent to Asp 92 but probably not linked ionically, form an ion pair dimer with their symmetry-related equivalents Arg 91 and Glu 90 across a 2-fold axis to a third molecule in the lattice.

It seems likely that at the intramolecular level, these interactions are partially responsible for the high stability that seems to be functional in this structure. It has been pointed out[36] that enzymes from thermophilic bacteria have abundant surface ion pairs which contribute to thermal stability. An 'exoskeleton' of organized charged groups could therefore be quite important in holding together the strands that form each domain of γ-crystallin II.

On the level of intermolecular contacts, not only hydrophilic residues are involved. The few relatively exposed hydrophobic side chains, such as Phe 11 and Tyr 51 are often found at lattice contact points (Phe 11 at a 2-fold near its symmetry-related equivalent). Similar interactions may occur in the normal lens and contribute to its supramolecular organization and control of protein concentrations. Differences in the balance of these polar and non-polar surface residues may be responsible for the different properties of the various γ-crystallins, for example, their relative abilities to cryoprecipitate. A comparative study of γ-crystallins is now being done in our laboratory to investigate these effects (parallel work is being done by Dr Y. Chirgadze[37,38]).

The nature of the molecular surface may also be important when considering the structure of the water in the lens. Eye lenses generally have a very low water content, particularly in the most central regions where, in mammals, γ-crystallins are most concentrated. The percentage of water correlates with the refractive power of the lens and its degree of softness and therefore its ability to accommodate.The charge interactions that fix the positions of polar side chains, making them so well defined in the electron density map, would lead to partial neutralization of charge, but by being fixed, the surface ions could still have a major effect in ordering local water. One of the roles of the crystallins may be to form hydration spheres and regulate the water content of the lens.

Sulphydryl arrangement and accessibility

It is surprising that a protein which must retain its conformation and seems to have a largely structural role should have evolved with six free sulphydryl groups . An intracellular protein of this size would be expected to have about two cysteine residues[39]. It was therefore interesting to examine the accessibility, reactivity and arrangement of these groups.

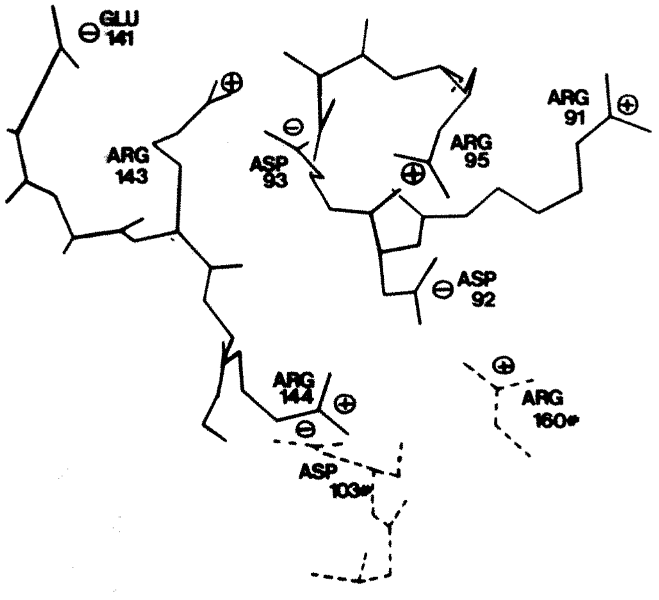

Fig. 7 An extensive network of charged groups on the surface of the molecule, centred on Asp 92. This and similar interactions may be partially responsible for the stability of the γ-crystallin molecule.

The three-dimensional structure demonstrates that not only do five of these groups lie in the same domain but three are also clustered closely together. Figure 4 indicates that Cys 23 and Cys 74 lie together on the same side of adjacent strands of a β-sheet in a position to form a disulphide bridge. Cys 18 also lies close by on the other sheet in the same domain, and this might also form an intramolecular disulphide bridge with Cys 23 in non-reducing conditions. Such intramolecular disulphide bridges would not radically affect the overall conformation of the molecule. Cys 15 and Cys 105, like Cys 23 and Cys 18, are on either strand b or c of the Greek key motif, and are therefore accessible to solvent. In the appropriate oxidizing conditions, these cysteines could form intermolecular disulphide bonds. In species such as the rat, where the core lens proteins undergo almost complete oxidation of protein sulphydryl[40,41], a combination of inter- and intramolecular disulphide cross-links must occur, involving such surface and clustered cysteines.

The two remaining cysteine residues, 32 and 74, are relatively buried in the structure. We observed early on in our study that extensive reaction in the crystals with small, reactive groups such as ionic mercury salts led to a rapid loss of isomorphism, and that reaction in solution led to precipitation. This did not occur if the mercury was coordinated with softer anions, attached to large groups (as in thiomersal) or part of a small hydrophobic cation like $EtHg^+$. The buried cysteine residues are not accessible to the large thiomersal group, whereas the small $EtHg^+$ can bind to both, causing only small changes in conformation, as the ethyl group does not greatly disturb the hydrophobic core of the molecule. It is probable that Hg^{2+} ions bind to Cys 32 and 74 but then, by production of $CysHg^+$, cause destabilization and possibly denaturation of the molecule. Such an irreversible covalent change leading to denaturation could be the first stage in a series of catastrophic and cascading events leading to the extensive polymerization and denaturation observed in senile nuclear cataracts. Whether these observations are relevant to human senile cataract must, however, await the chemical characterization of human γ-crystallin (Augusteyn *et al.*, unpublished results).

We have thus shown that although γ-crystallin II has a remarkably symmetrical structure which may confer stability on this protein in the normal healthy lens, the unusual arrangement of sulphydryls could contribute to the process of cataract if the reducing environment of the lens, including glutathione levels, were disturbed. Furthermore, the existence of a highly organized arrangement of charges on the molecular surface may be important in the organization of the crystallins and water in the normal transparent lens.

We thank Professor H. Bloemendal and Drs W. W. de Jong and L. Croft for sequence information on the βBp- and γ-crystallins respectively, and Dr J. Harding for useful and stimulating discussions. This research was supported by MRC grant no. 76/862.

Constraints on heavy neutrinos

Doug Toussaint & Frank Wilczek

Institute for Theoretical Physics, University of California,
Santa Barbara, California 93106, USA

If a heavy neutrino of mass 1.1 MeV < m < 14 MeV participates in the weak charged current coupling for the electron, then it can be produced in the Sun and decay in flight into an electron, a positron and a light neutrino. It is shown here that existing experimental bounds on low-energy interplanetary positrons severely constrain the heavy neutrino–electron coupling. Accelerator experiments severely constrain the coupling of still heavier neutrinos.

Several recent developments in high-energy physics and in astrophysics have reawakened interest in the question of neutrino masses. There have been experiments on the end-point energy in tritium decay[1] and on neutrino oscillations[2] which purport to show positive results. The tritium experiment is easier to quantify, and if correct shows that at least one of the neutrinos emitted in tritium decay with large amplitude has a mass of a few tens of electron volts. Also, some unified theories of strong, electromagnetic and weak interactions suggest that neutrinos are massive[3]. In these theories leptons are treated in parallel with quarks, except that the right-handed components of the neutrinos are $SU(3) \times SU(2) \times U(1)$ singlets (having neither strong, electromagnetic nor weak interactions) and so can acquire a large Majorana mass. In these theories we often find mass formulae of the form

$$m_\nu \propto m_q^2/m_N \qquad (1)$$

where m_ν is the neutrino mass, m_q is the mass of the corresponding charge 2/3 quark (for example, u quark for the lightest neutrino, c quark for the next lightest) and m_N is the Majorana mass. The quark–lepton analogy might also suggest small mixing angles among different neutrinos, analogous to the Cabibbo angle for quarks. Finally, observational evidence for non-luminous matter has become quite strong[4], reviving interest in suggestions that massive neutrinos could contribute significantly to the overall mass density in the Universe[5] and in

0028–0836/81/090777—02$01.00

galaxies and their haloes[5,6]. In these regards it is neutrinos with mass of a few tens of electron volts, and lifetimes longer than the age of the Universe, that are most significant. Heavier stable or quasi-stable neutrinos are ruled out by these astrophysical considerations. (However, if the neutrino mass gets above several GeV, these limits no longer apply, as noted by Lee and Weinberg[7].)

These considerations suggest that the lightest neutrino, coupling mainly to the electron, may have a mass of a few tens of electron volts. According to equation (1) we would expect the other neutrinos to be much heavier, and presumably unstable on cosmological time scales due to some coupling with the electron charged current through mixing. We will argue that existing observational evidence on the abundance of low-energy interplanetary positrons severely constrains the allowable mixing angles for neutrinos with mass $1.1\,\mathrm{MeV} < m < 14\,\mathrm{MeV}$. (Astrophysical constraints on very long-lived neutrinos which decay radiatively have been given by Cowsik[8].) Accelerator experiments restrict the mixing angles for still heavier neutrinos, and could lead to very stringent limits.

Our astrophysical limits are based on consideration of heavy neutrinos produced in the Sun and decaying in interplanetary space. Neutrinos of mass up to 14 MeV can be produced in the Sun through the decay ${}^8\mathrm{B} \to {}^8\mathrm{Be} + \mathrm{e}^+ + \nu$ in a side branch of the proton–proton chain. (These neutrinos are those searched for by R. Davis. He finds a factor three less than the lower theoretical estimate. We use the lower theoretical value here but appropriate factors of three may be applied.) If the coupling of the heavy neutrinos is a factor $\sin\theta_e$ of the total, then the expected heavy neutrino flux at Earth will be $F = \Phi \sin^2\theta_e g(m)$ where $2.4\times10^6 < \Phi < 4.5\times10^6\,\mathrm{cm^{-2}\,s^{-1}}$ is the flux calculated for massless neutrinos[9] and $g(m)$ is a factor taking into account the reduced phase space for ${}^8\mathrm{B}$ decay ($g(0) = 1$). The decay rate Γ for heavy neutrinos into electron, positron and light neutrino is obtained by scaling from the μ lifetime as

$$\begin{aligned}\Gamma &= \Gamma_{\mu\to e\nu\nu}(m_\nu/m_\mu)^5 \sin^2\theta_e h(m_e/m_\nu)\\ &= 5\times10^{-5}(m_\nu[\mathrm{MeV}])^5 \sin^2\theta_e h(m_e/m_\nu)\,\mathrm{s}^{-1} \qquad (2)\end{aligned}$$

where h is a phase-space factor with $h(0) = 1$. In the interesting range of parameters the lifetime of the heavy neutrino is so long that most of them decay outside the Earth's orbit. To calculate the flux of positrons at the Earth's orbit we simply multiply the neutrino flux by the probability of decay inside the Earth's orbit (actually this must be done energy by energy to take account of time dilatation).

Now we can compare these calculations with the relevant experiments[10–12]. According to the latter, the flux of positrons in interplanetary space at around 5 MeV kinetic energy is $\simeq 10^{-4}\,\mathrm{cm^{-2}\,s^{-1}\,sr^{-1}\,MeV^{-1}}$. This flux is consistent with estimates of positron flux from cosmic-ray secondaries, so we take it as an upper limit on the possible flux from solar neutrino decay. Comparing with our calculations, we find severe constraints on the mixing angle. For example, at $m_\nu = 2\,\mathrm{MeV}\ \sin^2\theta_e < 8\times10^{-5}$, at $m_\nu = 5\,\mathrm{MeV}\ \sin^2\theta_e < 5\times10^{-6}$, at $m_\nu = 10\,\mathrm{MeV}\ \sin^2\theta_e < 1\times10^{-6}$. The constraints continue to be quite severe until the mass gets very close to the kinematic limits—1.1 MeV for the $\mathrm{e^+e^-}$ decay and 14 MeV for production.

Neutrinos of mass <1.44 MeV would also be produced in the reaction $\mathrm{p + p + e^- \to d} + \nu$. The estimated neutrino flux from this reaction is $1.6\times10^8\,\mathrm{cm^{-2}\,s^{-1}}$, about two orders of magnitude larger than the flux from ${}^8\mathrm{B}\to{}^8\mathrm{Be}$, and because these neutrinos would have low energy, a larger fraction of them would decay inside the Earth's orbit. However, the experimental limit on positrons in this energy range is about two orders of magnitude higher than at 5 MeV, so the limit on $\sin^2\theta_e$ is only slightly better.

Dicus *et al.*[13] have derived constraints based on cosmological considerations which are complementary to ours. Heavy neutrinos which are long-lived are dangerous in cosmology: their decay can inject additional entropy into the Universe after nucleosynthesis, thus invalidating calculations of deuterium abundance; or their decay can introduce non-thermal background radiation contrary to observation; or their failure to decay can cause contraction of the Universe as we mentioned before. The limits of Dicus *et al.* seem to overlap ours, so that if we take both the big-bang cosmology and solar neutrino production seriously, neutrinos in the mass range 1.1–14 MeV seem to be ruled out altogether. We leave aside the bizarre possibility of a heavy neutrino which although above the threshold for $\mathrm{e^+e^-}$ decays only into three neutrino channels.

Accelerator experiments can also put constraints on heavy neutrinos, using the same principles (with the Sun replaced by an accelerator). To get an idea of the magnitudes, let us compare the mean free path l_m for weak interactions of a neutrino with kinetic energy E with the decay length l_d for decay into $\mathrm{e^+e^-}$.

$$\begin{aligned}l_m &\simeq (G^2 m_p E n)^{-1} = \frac{4\times10^{13}}{E[\mathrm{GeV}]}\ \mathrm{cm}\\ l_d &\simeq 6\times10^{17}\frac{E[\mathrm{GeV}]}{(m[\mathrm{MeV}])^6\sin^2\theta_e}\ \mathrm{cm}\end{aligned} \qquad (3)$$

Therefore, neutrinos with masses of 50 MeV or so might be more likely to decay yielding an energetic $\mathrm{e^+e^-}$ pair than to undergo normal weak interactions in a large detector. To make the comparison fair, note that other mixing factors appear in the relative production rates for heavy versus light neutrinos. If the neutrino beam is generated from π decays, a heavy neutrino with mass <35 MeV can come from $\pi^+\to\mu^+\nu$ with a mixing factor $\sin^2\theta_\mu$ measuring its participation in the muon charged current. Another source could be $\pi^+\to\mathrm{e}^+\nu$, with the usual kinematic suppression undone for heavy neutrinos: this would occur with probability $\sin^2\theta_e(m_\nu/m_\mu)^2$ of the ordinary π decay. Similar considerations apply to K-decay which also has larger available phase space and could therefore produce heavier neutrinos.

Note that heavy neutrinos produced in $\pi^+\to\mathrm{e}^+\nu$ decay would be largely helicity-flipped. If the neutrino mass is of Majorana type, then these helicity-flipped neutrinos would interact and decay as antineutrinos. The angular distribution of the $\mathrm{e^+e^-}$ pairs in the decay would be modified accordingly.

We have not examined carefully what quantitative conclusions can be drawn from existing experiments, but clearly heavy neutrinos with mass >50 MeV would have to appear with small mixing angles. It would seem that very sensitive experiments could be designed to look for ν decays in flight, in particular at a K-meson factory.

The effect of such a massive neutrino on the e/μ ratio in K_{l2} and π_{l2} decays has been calculated by Goldman and Kolb[14]. Recently Shrock[15] has proposed searching for unstable neutrinos or for characteristic energy shifts of the charged leptons in π_{l2} and K_{l2} decays, and Calaprice (S. Treiman, personal communication) has analysed deviations from universality in nuclear decays as possible signatures for large neutrino masses. These methods, of course, could in principle be sensitive to masses below 1.1 MeV.

We thank S. Treiman, S. Peale, E. Hones, R. Lingenfelter and E. Stone for useful conversations. This work was supported by NSF grant PHY77-27084.

ISRO Satellite Centre, Bangalore 560 058, India

The possibility of a permanent ring structure around the Sun was first pointed out by Brecher *et al.*[1] from evolutionary, physical and chemical considerations as well as constraints arising from observational astronomy related to Sun and its immediate neighbourhood. In particular, Brecher *et al.*[1] concluded that such a ring, located at ~4 $R_\odot$, must consist of refractory particles (graphite, for example) of size >10 km at ~1,000–2,000 K which, therefore, would emit thermal radiation peaking around 1.5–3.0 µm. We report here our attempt to detect the existence of this ring structure utilizing the IR observations taken during optimal viewing conditions of the total solar eclipse of 16 February 1980.

The experimental system consisted of a 6-inch $f/6$ newtonian telescope coupled to a celostat. The detector assembly consisted of a PbS detector, a chopper with its motor, a filter and a detector cooling box. The 1×1 mm PbS detector, cooled to liquid nitrogen temperatures had an NEP of 1.3×10^{-10} W at a chopping frequency of 1.042 kHZ. The interior of the cooling box was continuously purged by dry argon gas to prevent frosting of the filter–detector assembly. The IR filter with antireflection coating had a transmission of ~75% in the 1.9–2.8 µm range. The electronics consisted of a preamplifier (ORTEC model 5001), lock-in amplifier (ORTEC model 9501), chopper reference circuit and a tape recorder. The entire detector assembly was mounted on a moving carriage that enabled bi-directional scanning of the corona in the image plane, up to 5.5 $R_\odot$ on either side of the solar disk. The instrument was calibrated using the Moon at its various phases, and a black-body source.

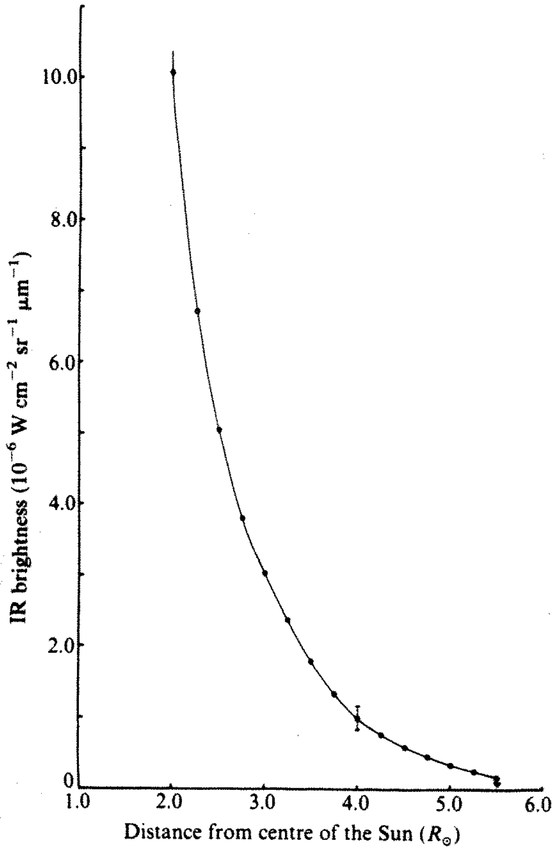

Fig. 1 The IR brightness of the solar corona in the equatorial plane from 2 to 5.5 $R_\odot$.

The observations were made from Hosur (long 75°09′04″; lat 15°00′12″) in Karnataka, India where the duration of the eclipse totality was ~2.5 min. During totality five scans in the image plane were carried out along 9.5°, 5.5°, 1.5°, −2.5° and −6.5° with respect to the solar equatorial plane. The spatial resolution of the instrument was 0.25 $R_\odot$. A continuous scan was made in the image plane.

Figure 1 shows the measured IR flux plotted as a function of distance from the centre of the Sun to a distance of 5.5 $R_\odot$, corresponding to the scan mode close to the equatorial plane. The absolute brightness of the outer corona has been deduced using calibration data on the Moon at its various phases. Comparison of the flux obtained in the present experiment at 3 $R_\odot$ with values obtained by Peterson[2] and MacQueen[3] indicate that the present value is larger by ~3.5 and 6 times their values respectively. These differences can be reconciled, as the present observations coincided with the period of solar maximum and the earlier observations of Peterson[2] and MacQueen[3] were made during the total solar eclipse of November 1966 at a time of solar minimum. Three independent observations[4] also indicate the variabilities in the IR emission from the solar corona. The first observation, using a coronagraph during a 1971 balloon flight, apparently revealed a weak and diffuse emission around 4.3 $R_\odot$ at 2.2 µm. The second observation, during a 1973 total solar eclipse revealed no evidence of a feature at 4 $R_\odot$ nor of a shelf of emission out to 6 $R_\odot$. In the third observation, a balloon flight after the 1973 eclipse also showed a weak feature, this time at 5 $R_\odot$ elongation, but no shelf. Our observations also imply that the IR corona is highly variable. Continuous monitoring of the solar corona in the near IR is, therefore, important for understanding interplanetary dust models.

At 4 $R_\odot$, the expected location of the ring, our measured flux is a factor of only 1.6 larger than the value obtained by Peterson[2]. We did not, however, observe the excess flux above the continuum reported by Peterson[2] and MacQueen[3]. The present observations therefore do not support the existence of a ring in the equatorial plane of the Sun, corresponding to a 3σ sensitivity of 10^{-7} W cm^{-2} sr^{-1} µm^{-1} at 2.2 µm in our detection system. Other scans which were conducted away from the equatorial plane have shown similar results, namely the absence of IR features above the level of detectivity. Thus our observations place definitive constraints on the hypothesis of Brecher *et al.*:

(1) The ring, if it exists in the equatorial plane between 2 and 5.5 $R_\odot$, has an IR brightness lower than 10^{-7} W cm^{-2} sr^{-1} µm^{-1} at 2.2 µm. The excess emission observed at 4 $R_\odot$ by Peterson and MacQueen cannot be ascribed to a 'stable' ring structure, because if the dispersion time for such a ring were of the order of 10^{13} yr we should have seen it in the present experiment.

(2) The present upper limit would also imply an upper limit to the total number of 10 km objects of ~10^8, based on the visual magnitude $m_v = +8$ to $+10$ for the individual objects as hypothesized by Brecher *et al.*

(3) If the ring resides at $R \gtrsim 5.5\ R_\odot$, the total mass in the ring is $\lesssim 3\times10^{25}$ g which in turn will limit the total number of 10 km objects (made of graphite with a density of 2 g cm^{-3}) to ~3×10^6. If the ring consisted of less refractory materials and were located at distances greater than 5.5 $R_\odot$ from the Sun, our experiment would not have detected it. If smaller particles with size <10 km, that are spiralling into the Sun, contribute significantly to the total IR emission of the solar corona at distances less than 5.5 $R_\odot$, it is possible that such radiation may mask the excess emission arising from a ring of larger particles with a sharp outer boundary within 5.5 $R_\odot$. But then the observation of an excess emission at times, makes the problem more enigmatic and interesting for future measurements.

0028–0836/81/090779—02$01.00

If a ring structure exists around the Sun between 2 and 5.5 $R_\odot$ in the equatorial plane, this experiment places an upper limit of 10^{-7} W cm^{-2} sr^{-1} μm^{-1} for its emission at 2.2 μm. Further, observations seem to indicate a high degree of variability in the near IR emission from the solar corona.

We thank the staff from the ISRO Satellite Centre for their cooperation, and the Department of Space, Government of India for Financial support.

Temperature dependence for the power outputs of *n*-CdSe liquid junction cells

J. F. McCann, M. Skyllas Kazacos & D. Haneman

School of Physics, The University of New South Wales, PO Box 1,
Kensington, New South Wales 2033, Australia

Thin film *n*-CdSe photoanodes have great potential as efficient and inexpensive electrodes in liquid junction photovoltaics[1–3]. This stems from the stability of *n*-CdSe in the S/S^{2-} electrolyte, its direct band gap[4] of 1.7 eV and the large barrier height, $\Phi_B(T)$, of ~1 eV at the *n*-CdSe–S/S^{2-} interface[5]. The recently reported 8% AM1 conversion efficiency for a cadmium chalcogenide thin film based cell[6] suggests that these low cost devices may soon compete favourably with the conversion efficiencies of the more expensive single crystal solid state photovoltaics. In view of the increasing practical importance of this system, the study of any parameter which may affect its performance is relevant. We report here the dramatic effect of temperature on the power outputs of *n*-CdSe based cells.

Single crystals of *n*-CdSe (Cleveland Crystals Inc.) were fabricated into electrodes by forming an ohmic contact on the back side of each crystal with In:Hg amalgam and soldering onto a copper wire. The crystals were mounted in epoxy resin, polished and etched by the usual techniques[1] before use. Thin films of *n*-CdSe were prepared on 1×3 cm^2 Ti strips by the electroreduction of Na_2SeSO_3 in the presence of a high concentration of Cd^{2+} (ref. 7). The films were annealed in a vacuum at 400 °C for 1 h. Several CoS counter electrodes were prepared by the method described by Hodes *et al.*[8]. The electrolyte used in this study consisted of S(1M)–Na_2S(1M)–Se(0.07M)–NaOH(1M) and was prepared with AR grade reagents and distilled water. During all experiments the electrolyte was continuously purged with N_2 and stirred. Cell current–voltage (*i–V*) curves were obtained by varying a load resistor between the *n*-CdSe and CoS electrodes. A 300-W General Electric ELH lamp was used to illuminate the semiconductor electrodes by a Schott KG-2 filter (intensity ~ 70 mW cm^{-2}).

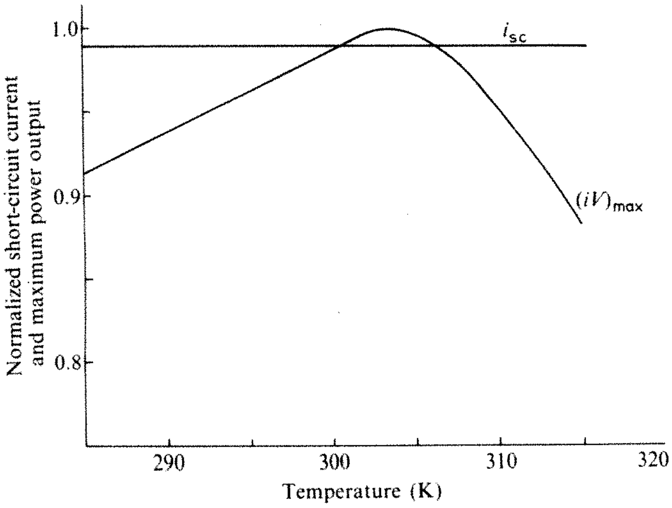

Fig. 1 The normalized short-circuit current, i_{sc}, and maximum power output, $(iV)_{max}$ of single crystal *n*-CdSe/S(1M)–Na_2S(1M)NaOH(1M)–Se(0.07M)/CoS as a function of temperature.

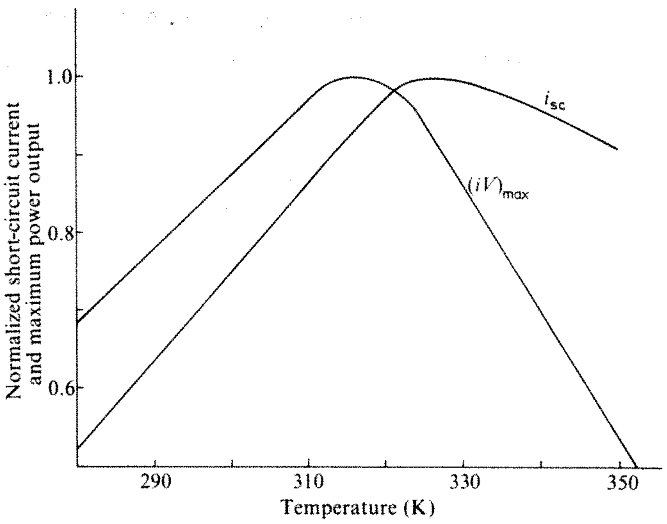

Fig. 2 The normalized short-circuit current and maximum power output of a thin film *n*-CdSe/S(1M)–Na_2S(1M)–NaOH(1M)–Se(0.7M)/CoS cell as a function of temperature.

The resistance of a cell with the electrodes separated by ~1 cm was measured by passing a sinusoidal voltage (Heathkit ET-3100 sine wave generator) of the desired frequency across two resistors (R_1 and R_2) which were in series with each other and with the cell. A PAR lock-in amplifier (model 124A) was used to measure the in phase signal, Z_R, differentially across R_2 (typically 1 Ω) and directly across the cell (resistance R_{cell}) which was kept at open circuit. The amplitude of the sine wave across the cell was kept <10 mV by adjusting the value of R_1. The value of R_{cell} was determined by comparing the voltage reading across R_2 with the voltage reading across the cell.

Series of *i–V* curves were determined for several *n*-CdSe cells over a range of temperatures. These were obtained by first cooling down the electrolyte in the single compartment cell, and gradually heating it on a heating mantle over a period of ~2 h. *i–V* curves were obtained at various temperature intervals and the electrodes were illuminated only while the curves were being recorded. To verify that the effects observed were due to temperature and not time, the solution was then allowed to cool down and *i–V* curves again recorded. The data obtained on cooling were equivalent to those obtained on the heating cycle. The open circuit voltages of both single crystal and thin film based cells dropped by ~2 mV per degree C as the temperature was increased, which is comparable with the decrease in V_{oc} typically observed in solid state photovoltaics for comparable illumination intensities. In the latter systems, this trend can be predicted from the relation for the open circuit voltage, $V_{oc}(T)$ as a function of temperature[5]:

$$V_{oc}(T)=\frac{nkT}{q}\ln\left[\frac{i_{ph}}{A^*T^2\exp(-\Phi_B/nkT)}+1\right] \qquad (1)$$

where q is the electronic charge, k is Boltzmann's constant, T is the absolute temperature, n is a factor which takes the non-ideal behaviour of the semiconductor into account, i_{ph} is the semiconductor photocurrent, and A^* is Richardson's constant for a given semiconductor. In the case of a photoelectrochemical cell, however, this relationship has to be modified to include the

0028–0836/81/090780—03$01.00

temperature dependences of the redox potential of the electrolyte, and the flat band potential of the semiconductor. These factors could result in a temperature dependence of the barrier height Φ_B. Variations in the semiconductor band gap and solution absorption with temperature could also have an effect on i_{ph}. The A^*T^2 term in equation (1) would also need to be modified to take the electron transfer probability through the Helmholtz layer into the electrolyte into consideration. In spite of these limitations of equation (1) when applied to a liquid junction photocell, the observed decrease in V_{oc} for n-CdSe in S/S^{2-} of 2 mV per degree C for increasing temperature is in agreement with the value predicted by this relation and could suggest that the modifications outlined above may not be very significant.

The typical effects of temperature on the short-circuit current and power outputs of both single crystal and thin film n-CdSe cells are shown in Figs 1 and 2 respectively. Although the short circuit current for the single crystal cell remains essentially constant over the temperature range, the power output of the cell exhibits a maximum at ~30 °C. This is due to a corresponding increase in the fill factor with temperature which counteracts the drop in V_{oc} and thus results in the maximum observed for the power output of the cell. The behaviour of the thin film cell shows a more dramatic temperature dependence. In contrast to the single crystal cells, the short-circuit current for this type of cell increases drastically up to about 50 °C. Experiments on several thin film electrodes have indicated that the short circuit current tends to level off beyond 50 °C rather than drop slightly as seen in Fig. 2. There is a corresponding improvement in the output power up to ~40 °C. However, due to the continuing decrease in V_{oc} and the levelling off of the short circuit current, the power output decreases rapidly at higher temperatures resulting in an optimum cell operating temperature of around 40 °C. We suggest that the striking effect of temperature on the short circuit current for thin film cells can be explained in terms of the dissolution kinetics of sulphur formed at the photoanode. Because of the polycrystalline nature of these films the electrolyte penetrates the fine pores. As the oxidation of sulphide progresses, the sulphide ion concentration within the pores becomes depleted. Hence the dissolution of sulphur formed within the pores, which occurs according to the reaction:

$$\mathrm{S(solid)} + \mathrm{S}_x^{2-} \rightleftarrows \mathrm{S}_{x+1}^{2-} \text{ (in solution)} \qquad (2)$$

is limited by the rate of diffusion of sulphide ions into the pores from the bulk of the solution and partial passivation of the electrode occurs. The rate of sulphur dissolution increases with temperature until it is no longer a limiting factor. This causes the corresponding increase in the short circuit current observed up to ~50 °C (see Fig. 2). Films grown by another technique (D. Miller and D.H., unpublished results) also show the temperature behaviour described above.

As a further test of the above hypothesis, experiments were carried out over a range of light intensities on a CdSe film grown by the latter technique. The kinetics of sulphur dissolution would be expected to have a much less important effect at comparatively low light intensities. Measurements between 0 and 40 °C showed that the rate of increase of the short circuit current with temperature dropped from 0.33 at a light intensity of ~140 mW cm^{-2} to 0.15 at 70 mW cm^{-2} to 0 at 0.5 mW cm^{-2}. This behaviour is therefore consistent with the sulphur dissolution hypothesis.

The effect of temperature on the electrolyte resistance was also examined as this may also influence the i–V characteristics of n-CdSe cells. Figure 3a shows the resistance of a n-CdSe/S–S^{2-}–Se–OH^-/CoS cell plotted as a function of frequency both in the dark and under illumination, and shows that the resistance levels off at frequencies ≥20 kHz. This graph also illustrates the decrease in the net resistance of the semiconductor on illumination which is apparently due to a reduction in the resistance of the space charge region and an increase in the photoconductivity of the semiconductor bulk.

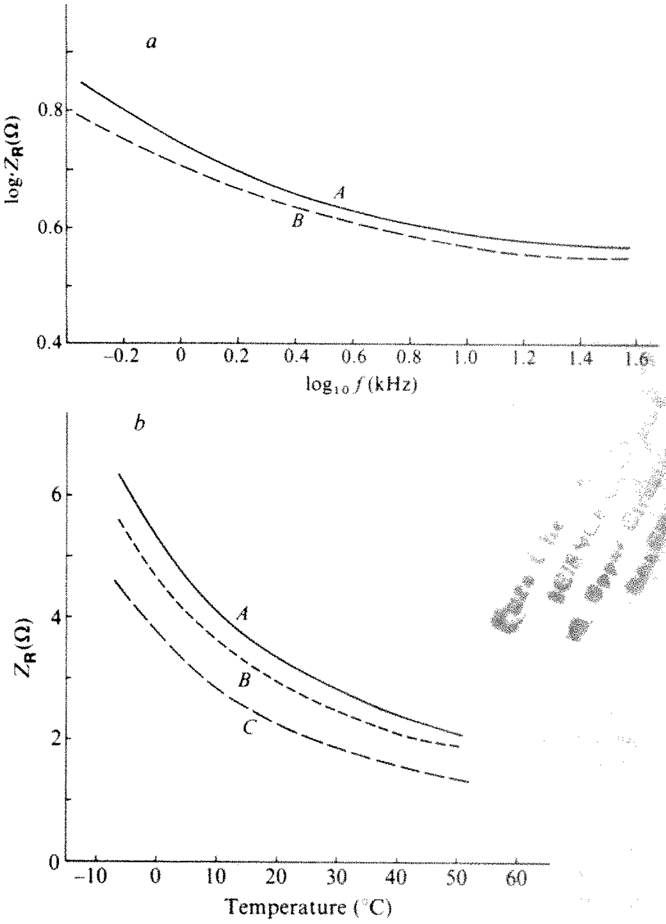

Fig. 3 a, The real component of the impedance, Z_R, of a thin film n-CdSe/S(1M)–Na_2S(1M)–NaOH(1M)–Se(0.7M)/CoS cell plotted against frequency f (in kHz): A in the dark and B under illumination; T = 22.5 °C. b, Z_R at 28 kHz versus temperature for a thin film n-CdSe/S(1M)–Na_2S(1M)–NaOH(1M)–Se(0.7M)/CoS cell: A in the dark and B under illumination. C, Pt–Pt cell in the same electrolyte.

Using an input frequency of 28 kHz, the above cell resistance was then measured as a function of temperature and compared with the results obtained using two platinum electrodes in the S/S^{2-} electrolyte. These results are presented in Fig. 3b. Again, the decrease in cell resistance on illumination of the CdSe can be observed in curves A and B. These curves also show the significant drop in cell resistance with increasing temperature. The parallel trend obtained with the two platinum electrodes (curve C) indicates that the temperature dependence is predominantly due to the electrolyte resistance rather than the semiconductor resistance varying as a function of temperature.

The above results therefore suggest that the changing resistance of the electrolyte as a function of temperature would be expected to influence the shapes of the cell i–V curves obtained for liquid junction solar cells. In fact, for the illuminated CdSe thin film solar cell used here, this resistance is seen to change from ~4.6 Ω at 0 °C to ~2 Ω at 50 °C. A significant increase in the fill factor of the cell i–V curves would be expected over this temperature range and was, in fact, observed in a previous study[5]. Another factor which may also influence the fill factor as a function of temperature is the change in the polarization of the CoS counter electrode with temperature. This latter effect was not examined in the present study but the Weizmann group have shown that polarization at a CoS counter electrode decreases with temperature[10]. This would also improve the fill factor of a cell with temperature.

The above results emphasize the importance of controlling the operating temperatures of n-CdSe liquid junction cells particularly those based on thin films to obtain the maximum possible photo-conversion.

Zoned aluminium distribution in synthetic zeolite ZSM-5

R. von Ballmoos & W. M. Meier

Institut für Kristallographie und Petrographie, ETH Zürich, 8092 Zürich, Switzerland

ZSM-5, a prominent member of the new generation of high silica zeolites, is a potential catalyst. The activity of ZSM-5 type synthetic zeolites with respect to acid-catalysed reactions is a linear function of the Al content[1] which can assume extremely low values, but in catalytic applications is typically 1–3 Al per unit cell containing 96 Si + Al atoms. We now present substantial evidence that the Al distribution in ZSM-5 crystals is non-uniform. We first noted zoning of Al in ZSM-5 when examining scanning X-ray micrographs (Al Kα) of 50 μm crystals. The comparatively large crystals necessary for detailed measurements of Al concentration profiles using electron probe analysis suggest that Al is invariably concentrated in the rim portion of the crystals. No comparable zoning has been reported previously for zeolites.

ZSM-5 is synthesized in siliceous systems containing tetrapropylammonium (TPA) and sodium ions[2]. The Si/Al ratio of ZSM-5 ranges from ~10 to >4,000 (ref. 1). Such figures refer to bulk composition of the crystals which typically do not exceed a few micrometres in size. The crystal structure of ZSM-5 (ref. 3) and the structural properties of its aluminosilicate framework have been described elsewhere[4–6]. X-ray structure analysis could not be expected to provide information on the arrangement of the relatively few Al atoms and a uniform distribution has been assumed.

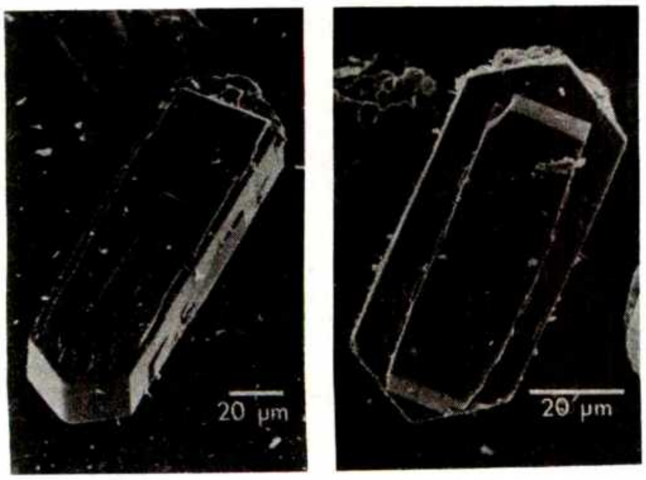

Fig. 1 Scanning electron micrographs of typical large ZSM-5 crystals. Gel particles are visible at the upper left.

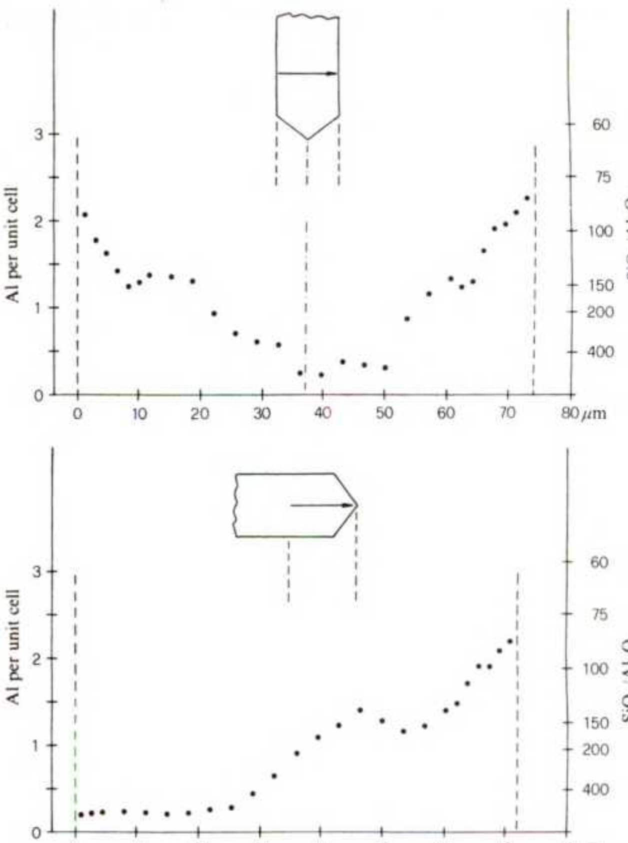

Fig. 2 Two perpendicular profiles of Al concentration across a section of a ZSM-5 crystal determined by microprobe step scans (shown in the inserted outline).

Appropriate conditions for growing large ZSM-5 crystals were determined, using dilute systems containing ~40–60 mg of solid per 10 cm^3 of solution. A suitable molar composition is around $11SiO_2:Al(NO_3)_3:2NaOH:72(TPA)OH:3{,}300\ H_2O$. Crystallizations were carried out in small steel autoclaves (25 cm^3) at 200 °C for 5 days[7]. The largest crystals obtained were 60–200 μm. Figure 1 shows scanning electron micrographs of typical crystals which appeared invariably twinned. All solid products of the crystallizations contained a considerable amount of gel. The Si/Al ratio of ~3–4 for the gel contrasts strongly with that of the crystals with bulk Si/Al ratios of 50–100. X-ray powder diffraction patterns were used to identify the ZSM-5 crystals.

Five specimens were filled into holes of 4 mm diameter in an acrylate disk. The holes were then filled with an epoxy resin (Epotek 330) which was then cured overnight at 60 °C. Grinding was completed with 0–3 μm diamond paste on a lapping wheel. The sample disks were cleaned with hexane and stored in water-free atmosphere. All samples were beryllium coated, and for some a very thin film of aluminium was first applied to assure better contact of the beryllium coating. Crystals of the silica end member of the ZSM-5 compositional series ('silicalite'[8]) were also prepared to monitor possible aluminium contamination. Electron microprobe scans used an ARL-EMX instrument at 15 kV, 0.08 μA sample current, a beam diameter of 0.8 μm producing an analysis volume of about 2 μm^3 and an average counting time of 8 s for each point, with crystal spectrometers (ADP and RAP). Orthoclase was used as a standard and the computer programs EMX and EMMA were used to process the data. Step advancement was mechanical at intervals of 1.8 or 3.5 μm along a straight path. Only true cross-sections through the core of the crystal and oriented approximately parallel or perpendicular to *c* were analysed. Scans were taken crosswise for better centering.

A total of 60 scans were made of 40 large ZSM-5 crystals with representative Si/Al bulk ratios of 50–100. All Al concentration profiles showed pronounced zoning as in Fig. 2. The Al concentration in the core was invariably below that in the rim. Minimum and maximum concentrations of Al within a ZSM-5 crystal frequently differ by a factor of 5 or more. The most pronounced zoning, with Al concentration in the rim exceeding that in the core by ≫10, was observed in Fig. 3. Core concentrations were often found near 0.2 Al per unit cell. In some crystals the Al concentration in the core was not above a detection level of 0.05 Al atoms per unit cell. Usually zoning is monotonic from a siliceous core to an Al-rich rim but some waviness (Figs 2, 3) could frequently be observed. (More details are presented elsewhere[7].) All zoning was essentially symmetric.

Strong zoning of this kind has not so far been found in zeolites. There is a relative increase in the Si/Al ratios from core to rim of large NaX crystals of a few per cent[9]. This zoning in NaX is reversed and much less striking than that in ZSM-5. Crystals of natural faujasite, phillipsite and offretite were found to be uniform[10]. On the other hand, chemical zoning is present in feldspars of the plagioclase series[11].

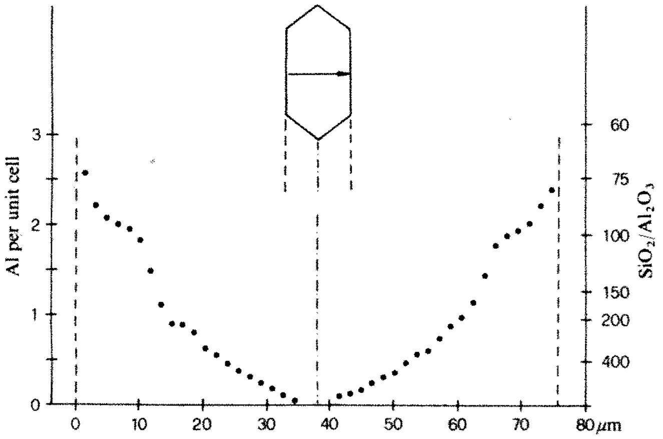

Fig. 3 Example of a scan which exhibits Al-zoning with extreme concentrations differing by a factor of more than 10. The innermost core concentration is around the detection limit of 0.05 Al per unit cell.

The presence of Al-rich solid gel in the products might suggest that the increased Al content in the rim is associated with dissolution of gel particles which enhances the Al content of the solution towards the end of crystallization. This would imply crystal growth from the liquid phase.

Although the zoning observed in large ZSM-5 crystals does not necessarily apply to much smaller crystals, their bulk compositions should be interpreted with caution.

Volcanism and the dynamics of open magma chambers

Stephen Blake

Lunar and Planetary Unit, Department of Environmental Sciences, University of Lancaster, Lancaster LA1 4YQ, UK

The repeated eruption of many volcanoes is now accounted for by events taking place in a subterranean magma chamber, which is 'open' in the sense that the inflow of material to the chamber from below leads to a magma pressure P which exceeds the lithostatic pressure P_L by an amount greater than the tensile strength of the chamber walls (σ) before the contents of the magma chamber have reached thermodynamic and geochemical equilibrium. This is the condition which must be satisfied when an eruption occurs. We have now derived a relationship giving the critical volume of added material (ΔV) required to cause an eruption as a function of magma compressibility and the volume by which the chamber expands.

Geochemical, petrological and stratigraphic studies of lava piles at individual volcanoes have demonstrated than many sub-volcanic magma chambers are open systems where an evolutionary trend controlled by crystal fractionation is modified by the episodic influx of less evolved magma[1–4]. Disequilibrium phenocrysts and glasses in some lavas and ejecta also show that magma mixing has preceded eruption[5–10]. Such an open system of replenishment and eruption extends the lifetime of a chamber by buffering heat loss and is capable of chemically[11] and thermally[12] determining the evolution of the magma, depending on the fluid properties and dynamics of the magmas involved[13,14]. In addition to their petrological significance, open magma chambers are important volcanologically. The inflation of volcanoes, often accompanied by seismic activity, is attributable to the influx of magma into a sub-volcanic storage system. Eruption begins when some critical amount of magma has accumulated causing the reservoir to burst[15–19] and deflation typically accompanies withdrawal or eruption of magma[20].

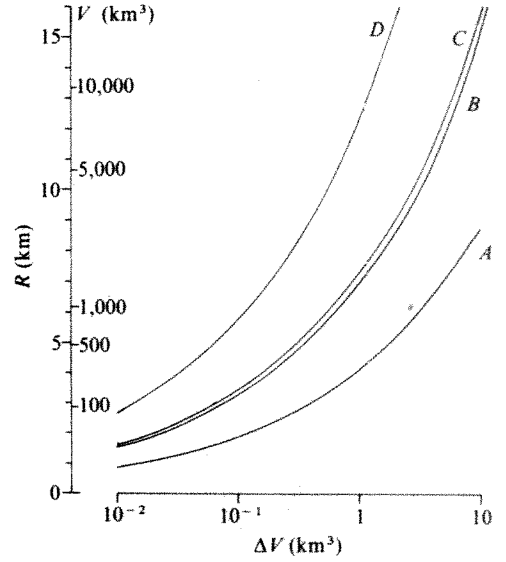

Fig. 1 The volume of magma, ΔV, which must be introduced into a chamber of constant volume, V_c, to trigger eruption according to $\Delta V/V_c = \sigma/b$. Also plotted is the radius, R, of a spherical chamber having volume V_c, but other geometries may be considered. Curves A and B, olivine basalt $b = 14$ GPa; C and D, andesite $b = 80$ GPa; A and C, strong volcano $\sigma = 50$ MPa; B and D, weak volcano $\sigma = 10$ MPa. For each case the critical values of σ/b are: A, 3.6×10^{-3}; B, 6.25×10^{-4}; C, 7×10^{-4}; D, 1.25×10^{-4}.

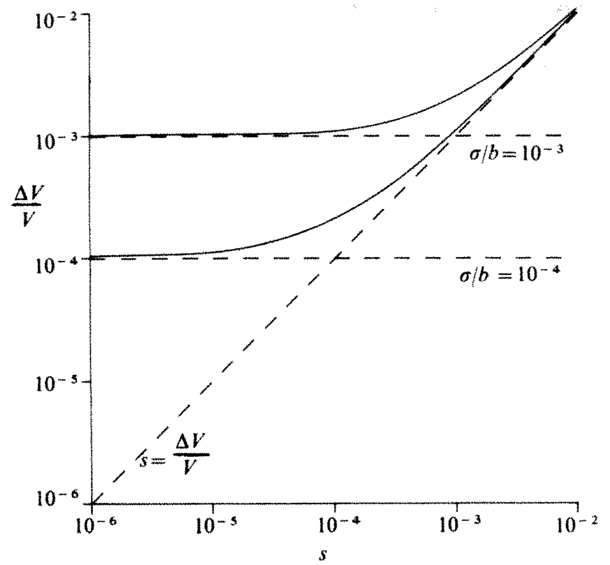

Fig. 2 Allowing a chamber to expand to a size $V_c\,(1+s)$ before eruption causes the critical ratio $\Delta V/V_c$ to increase according to $\Delta V/V_c=\sigma/b(1+s)+s$, which is shown by the heavy lines for the cases σ/b equal to 10^{-3} and 10^{-4}. When $s\ll\frac{\sigma}{b}$, $\frac{\Delta V}{V_c}\rightarrow\frac{\sigma}{b}$, approximately the case of a constant volume chamber; when $s\gg\frac{\sigma}{b}$, $\frac{\Delta V}{V_c}\rightarrow s$ and is independent of σ and b.

First, consider a constant-volume magma chamber which in equilibrium conditions (lithostatic pressure) contains a volume of magma V_c. When additional magma of volume ΔV is introduced, the contents of the chamber must become compressed to accommodate the new magma (an assumption which will be justified later). The compressed magma will occupy the volume V_c at a pressure P ($>P_L$), placing the chamber walls under tension. P and ΔV are related by the constitutive equation of the magma

$$V_c=(V_c+\Delta V)\exp\left[-(P-P_L)/b\right]$$

where b is the bulk modulus of the magma and ΔV is measured at P_L. The critical condition is arrived at when $P-P_L=\sigma$ which, for most rocks, lies in the range 10–100 MPa (ref. 21). The strength of volcanoes is, however, reduced by structural defects resulting from fragmental layers, vesicular and jointed lava flows, dyke and sill complexes and a generally stratified structure. Previous workers[19,22,23] have used values for the tensile strength of volcanoes in the range 10–50 MPa. Values of b have been calculated from the seismic wave velocities and densities of rock melts measured by Murase and McBirney[24] and are found to vary from 14 GPa (Galápagos Islands olivine basalt, 1,200 °C) to 80 GPa (Mount Hood andesite, 1,000 °C). The relative magnitudes of σ and b (that is, $\sigma/b\sim10^{-3}$) simplify the critical condition required for failure of the chamber walls to

$$\frac{\Delta V}{V_c}=\frac{\sigma}{b}$$

When the walls have failed, escape of magma is driven by decompression until magmatic pressure within the chamber has returned to lithostatic and only the stable volume of magma V_c is present. The expelled volume, V_e, is therefore equal to ΔV, as decompressional expansion on eruption is negligible.

Given the bulk modulus of a magma (which varies with composition and temperature) and the tensile strength of the volcano of interest, the erupted volume, being approximately equal to the volume required to trigger an eruption, is proportional to the size of the associated magma chamber.

Figure 1 depicts the relationship between ΔV required to trigger eruption from a spherical chamber of radius R and volume V_c. For basaltic volcanoes (Fig. 1, curves A, B) with $0.01\leqslant V_e<1$ km^3, chamber radii of 1–7 km are predicted, in good agreement with the sizes of exhumed gabbroic plutons[25], the seismically determined sizes of basic magma bodies in the upper crust[26] and the areal dimensions of calderas at stratovolcanoes. For a given chamber size and strength, the larger bulk modulus of cooler andesitic magma causes ΔV to be less than that required by a basaltic magma (Fig. 1, curves C, D). The range of V_e for both magma types is essentially the same, however, which therefore implies larger chambers at andesitic volcanoes ($R<12.5$ km) than at basaltic ones, a conclusion which seems to be substantiated, as dioritic and tonalitic plutons are often larger ($R<15$ km) than gabbroic plutons ($R<5$ km).

The assumption that V_c remains constant may not always be appropriate. If s is defined as the fractional volumetric expansion of the chamber, the critical condition for eruption becomes

$$\frac{\Delta V}{V_c}\simeq\frac{\sigma}{b}(1+s)+s$$

Consequently, the critical ratio $\Delta V/V_c$ is dependent on the relative magnitudes of s and σ/b (Fig. 2). The amount of expansion which a given chamber experiences will depend on its host environment. In unfractured competent country rock, dilation of the chamber results from elastic deformation of the wall rocks. As the compressibility of solid rock is up to an order of magnitude less than that of silicate melts[24] the chamber volume will not be significantly increased and $s<\sigma/b$. Accordingly, newly introduced magma is most easily accommodated not by an increase in chamber volume, but by compression of the magma itself. In such cases the constant volume model as discussed above is a valid simplification and $\Delta V/V_c\simeq\sigma/b\simeq10^{-3}$ adequately describes the critical condition for these eruptions (Fig. 1).

High degrees of chamber enlargement ($s>\sigma/b$) are thought to be due to the creation of new reservoir space by crack opening, filling and propagation such as in the rift zones of the Kilauea volcano[27,28]. Conditions at Kilauea and many other mature volcanoes are favourable for this type of behaviour because the magma chamber resides in a readily fissured lava pile. During these intrusive episodes, surface deformation is manifest (refs 15, 29–31).

The effect on the critical condition of allowing chamber expansion (creation of additional storage space) is shown in Fig. 3 for the case $\sigma/b=10^{-3}$ and $s=0$, 10^{-4}, 10^{-3} and 10^{-2}. When s exceeds σ/b, the factor controlling the onset of eruption (the value of ΔV) becomes the new size of the reservoir and is largely independent of σ/b. In these cases, the use of V_e and the

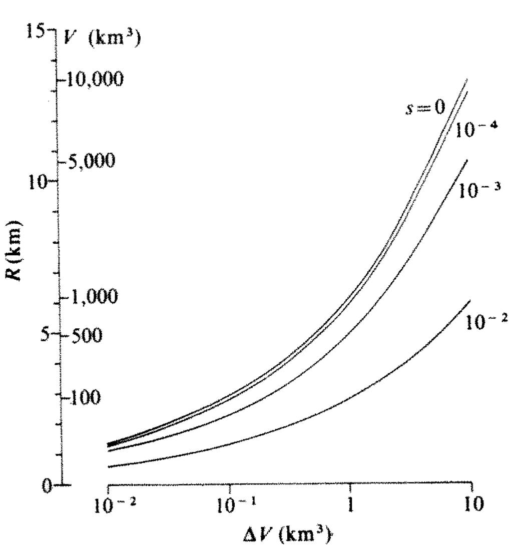

Fig. 3 The effect on ΔV of permitting chamber expansion $s=0$, 10^{-4}, 10^{-3} and 10^{-2} for chamber radius R, volume V_c and $\sigma/b=10^{-3}$. When $s\geqslant\sigma/b$, chamber expansion causes a significant increase in ΔV for a given chamber size (see Fig. 2).

assumption of a constant volume condition $(s \sim 0)$ would provide a large (up to an order of magnitude) overestimation of the stable chamber volume. For example, 10 km^3 of basaltic magma must be supplied to (and will later be erupted from) a 6.2-km radius chamber with volume 1,000 km^3 which has the ability temporarily to increase its storage capacity by as little as 1% (Fig. 3, $s = 10^{-2}$) whereas only 1 km^3 is required to trigger eruption from the same chamber if this additional space cannot be made available (Fig. 3, $s = 0$). Furthermore, caldera collapse or other tectonic effects will, by reducing the chamber volume to less than V_c, cause V_c to exceed ΔV. These effects have influenced activity in the Icelandic rift zones[32]. As V_c and particularly s, may vary over even a short span of a volcano's history, such tectonic influences will account for some of the variability between the amounts of magma erupted from the same volcano in successive eruptions.

Although basaltic magmas in plutonic conditions are generally believed to be undersaturated in volatile components, some eruptions may be related to chambers in which a free volatile phase has evolved. Because a gas is much more compressible than liquid magma, a given increase in P can be obtained by introducing a relatively small volume of magma or a relatively large volume of vapour. The critical value of ΔV is therefore virtually unaffected by the presence of a gas phase. Eruptions which are triggered by magma mixing[10] are therefore deduced to be triggered solely by the increased fluid pressure resulting from injection of (ΔV) new magma and not by any vesiculation process. Basalt–rhyolite mixed magmas have been erupted irrespective of the water content of the rhyolitic magma. Although the rhyolitic liquids involved in the Askja 1875 and Novarupta 1912 mixed pumice eruptions are believed to have been at or near saturation with H_2O contents of 3 and 5–6 wt%, respectively[33,34], much drier mixed lava flows are not uncommon[6].

The mechanisms discussed above serve as a general model on which to base concepts of stratovolcano development and seafloor spreading rates. Active periods, separated by repose periods of less than ten to hundreds of years and characteristic of a given volcano[35] are regarded as being associated with the uprise of magma at rates of several cubic metres per second over periods lasting up to several years, during which the critical amount of magma may be accumulated and eruption triggered more than once. As $\Delta V \simeq V_c$, volcano growth rates are equivalent to the upward magma flux rate beneath the volcano which is in turn governed by magma generation, accumulation and uprise dynamics. When related to an absolute time scale, the evolution and growth of stratovolcanoes and mid-ocean ridges are a potential tool with which to examine these magmatic processes[1–4,36–39].

Seismic quiescence in the Western Hellenic Arc may foreshadow large earthquakes

M. Wyss

CIRES, University of Colorado, Boulder, Colorado 80309, USA

M. Baer

Institute of Geophysics, ETH-Hoenggerberg, CH-8093 Zürich, Switzerland

South of Crete, the seismicity rate was constant in space and time between 1950 and 1978, but in the Western Hellenic Trench the rate was the same as that south of Crete until 1962, whereupon it decreased by 80%. We now suggest that the anomaly constitutes a warning of large earthquakes within the coming decade.

Studies[1,2] of the events preceding 20 earthquakes of magnitude greater than 6.0 have shown decreases of about 50% in the frequency of small earthquakes for several years before the main shocks. This was for example the case in the years preceding a Hawaiian earthquake of magnitude 7.2, where the decrease in seismicity was accompanied by two other precursor phenomena—relaxation of crustal strain and a change of seismic velocity[3]. Our hypothesis is therefore that a significant decrease of seismicity rate within a given volume is a sign that preparations have begun for one or more major earthquakes within that volume.

The region surrounding the Aegean Sea has the highest seismicity rate in western Eurasia[4], and its tectonic complexity has been widely discussed[5–11]. There is general agreement that the Hellenic trench–island arc system is a clear tectonic unit, that subduction occurs along it and that it can be regarded as a plate boundary. The direction of convergence is roughly perpendicular to the Western Hellenic Arc and approximately parallel to its eastern segment[6]. The rate of convergence may increase from west to east and is estimated to be between 2.5 and 7 cm yr^{-1} (ref. 6). Assuming that no substantial aseismic creep occurs, these consumption rates imply that enough strain energy has been stored here during loading cycles of the order of 100–200 yr to produce large earthquakes.

The time of the last very large ruptures along the Hellenic plate boundary is a matter of debate. Eight earthquakes of magnitude $\geqslant 7.75$ occurred in this area between 1805 and 1926, but most authors consider that these events occurred at depths of 100 km and locations about 100 km north of the plate boundary[12]. By this interpretation the plate boundary has not been ruptured in great events for about 200 yr, which would imply that 5–15 m of potential displacement have been stored. However, we propose the data on the destruction[18] caused by these large earthquakes to mean that these events were shallow ruptures of the plate boundary[20]. According to our interpretation, all the Hellenic plate boundary, except a 150-km segment west of Crete, was ruptured between 1805 and 1926.

0028-0836/81/090785—03$01.00

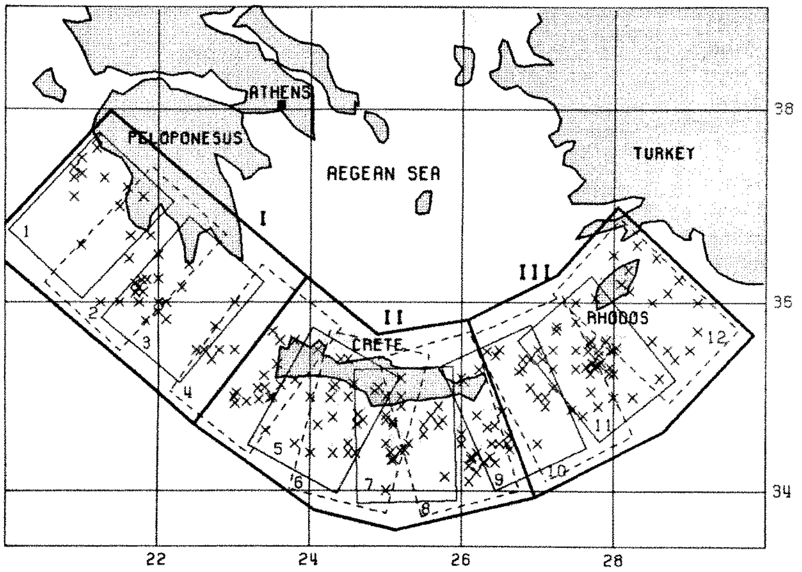

Fig. 1 Epicentre map of all earthquakes used (1950–78, 5.0 mag, $0 \leq$ depth ≤ 100 km) in the seismicity study of the Hellenic arc. Subvolumes for which seismicity rates as a function of time were determined separately are labelled 1–12. Large segments of the arc for which cumulative seismicity is shown as a function of time in Fig. 2 are labelled I, II and III.

We therefore estimate the potential earthquake slip stored at present to be $\sim$2.5–6 m (depending on the location along the arc). We conclude that, according to either interpretation, the Hellenic arc could reasonably be expected to be capable of very large earthquakes at the present time.

To determine whether any part of the arc is in a preparatory stage to rupture we studied the rate of occurrence of shallow earthquakes (0–100 km depth) as a function of space and time. A complete, pooled[13–15] data set for earthquakes of >4.9 mag was obtained for the period 1950–78. Analysis of cumulative numbers of earthquakes as a function of time showed that their overall rate of incidence in the Hellenic Arc decreased slightly after 1962. To determine the portion of the plate boundary responsible for this change we examined seismicity rates within 12 random overlapping volumes, defined in Fig. 1. Three facts became evident: (1) The seismicity rates in the neighbouring volumes 5, 6, 7 and 8 were the same to within 10%; they were approximately constant over the 28-yr period; and they were relatively high (1.5 events yr^{-1}) for this island arc. (2) Volumes 1–3 showed a common pattern of high rates ($\sim$1.5 events yr^{-1}) for the first 12 yr followed by a much lower rate (0.5 events yr^{-1}) during the remainder of the period. (3) A mixture of rates and patterns existed in volumes 9–12. Based on these observations, subvolumes of the arc with similar patterns were merged for further study of the seismicity rates.

Figure 2 shows the cumulative numbers of earthquakes as a function of time for the super-volumes designated I, II and III in Fig. 1 which are of similar dimensions (Fig. 2). The seismicity rate in these three volumes was the same up to the early 1960s, after which time volume II continued to produce earthquakes at the same rate as before, while volume I showed a highly significant decrease of seismicity to about 20% of its previous rate. We interpret this decrease of seismicity to be an anomaly precursory to one or several large earthquakes in volume I. The data of volume III are less clear, but an anomaly may have existed there since about 1970. We conclude that the greatest likelihood of very large earthquakes exists in the western part of the Hellenic Trench.

The largest length of the arc segment which may be ready for rupturing is approximately 400 km (volume I and immediately adjoining volumes containing high seismicity). Based on the destruction caused by the great earthquakes which occurred in the Western Hellenic Trench during the nineteenth and early twentieth centuries[18], we estimate the most likely length of future ruptures to be about 100 km. Using the hypothesis that the seismicity anomaly in the Western Hellenic Trench represents a precursor, and assuming that the precursor time is correlated with anomaly dimension, we expect that the sequence of large earthquakes will start between 1980 and 1991. Using seismicity data alone, we cannot estimate the time of occurrence more accurately than this because of the scatter in the data defining the anomaly dimension versus precursor time relation[1].

We expect an earthquake with the following source parameters to rupture the Hellenic arc plate boundary: location, near 23.5°E; size, lengths = 100 ± 50 km, magnitude 7.75 ± 0.5; occurrence, $1980 \leq T_0 \leq 1991$.

Although precursor seismicity patterns cannot be identified with certainty along the other segments of the Hellenic Trench, it seems reasonable to expect large earthquakes there also. However, this prediction should not be made without emphasizing the rudimentary nature of our understanding of the processes which lead to earthquakes. Even though the number

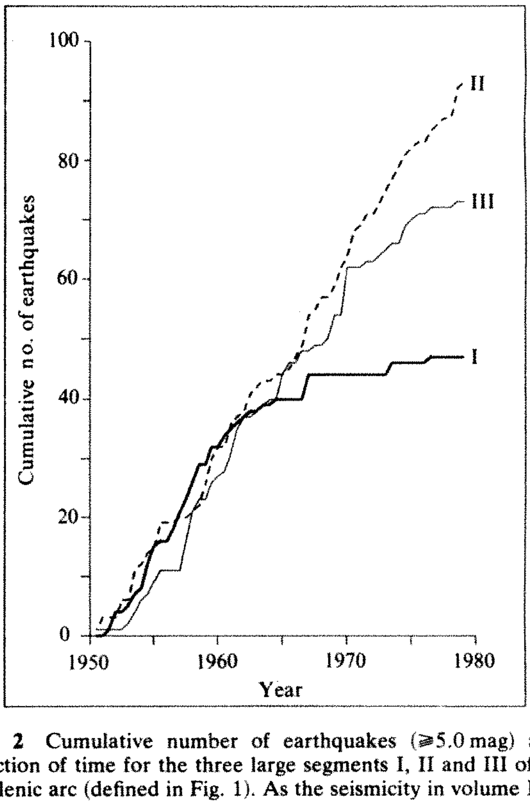

Fig. 2 Cumulative number of earthquakes (≥ 5.0 mag) as a function of time for the three large segments I, II and III of the Hellenic arc (defined in Fig. 1). As the seismicity in volume III is dominated by swarms (steps in the curve), we can reach no conclusion for this region. Note that the seismicity rates in I and II are closely similar up to 1962, after which time the rate in volume I is reduced to 20% of this rate while the rate in II continues at the pre-1962 level. The establishment of the World Wide Standard Seismograph network did not affect seismicity resolution in the area because the location capability is mostly based on European stations.

of well documented seismicity quiescence precursors is increasing, we do not know whether it is possible for seismicity quiescence anomalies to be terminated without a main shock.

Nevertheless, we believe that precautionary measures are warranted, although we are aware of the possible negative effects of broadcasting an earthquake prediction[19]. Ohtake *et al.*[16], about 2 yr before the 7.8 mag Oaxaca earthquake in 1978, showed that quiescence had begun in the Oaxaca gap in mid-1973, but their report produced no constructive action and was, in fact, ultimately detrimental to the area concerned. We hope that previous mistakes will not be repeated in the case of the Hellenic Trench and that scientific surveillance of the area will be started.

Clement G. Chase

Department of Geology and Geophysics, University of Minnesota,
Minneapolis, Minneasota 55455, USA

The Juan de Fuca, Rivera, Cocos and Nazca plates in the eastern Pacific are small fragments remaining from the fragmentation and partial subduction of the long, narrow Farallon Plate which began as early as 55 Myr ago[1]. This fragmentation apparently resulted from interaction of the very irregular Pacific–Farallon ridge with the uneven coastlines of the American Plate[1–4] and involved the formation of ridge–trench transforms[5], creation of new spreading centres[6], ridge jumps[1,7,8], deactivation of subduction zones[2] and other phenomena[1]. We present here magnetic evidence that a fifth small fragment of the Farallon plate is preserved in the eastern Pacific off the coast of Baja, California. Its preservation is the result of an eastward jump of the Pacific–Farallon ridge ~12.5 Myr ago which was preceded by asymmetric spreading and perhaps pivotal subduction[1]. Menard[1] first suggested this idea and showed that anomaly 5B is symmetric and parallel to a linear trough trending southwards from Guadalupe Island. He named the small fragment of the Farallon plate preserved between this trough and the margin of Baja California to the east, the Guadalupe plate[1]. We show that both anomalies 5B and 5C symmetrically flank the Guadalupe trough. Our results and conclusions are not based on new magnetic data, but rather on reinterpretation of aeromagnetic profiles published by Taylor *et al.*[9].

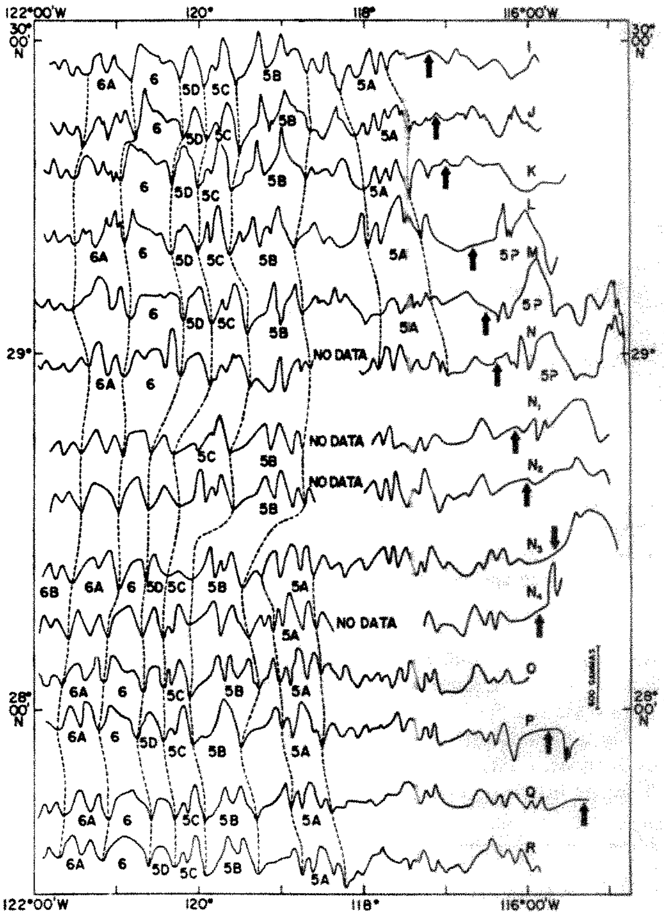

Fig. 1 Original data and interpretation of Taylor *et al.*[9] reproduced exactly. Arrows indicate the location of the 1,000-fathom bathymetric contour.

Figure 1 shows the data of Taylor *et al.*[9]. This area of the eastern Pacific was first studied by Krause[10] who recognized lineated magnetic anomalies east of Isla Guadalupe. Later studies[2,11] confirmed their presence, but as Atwater[2] states "near Guadalupe Island, (the magnetics) lack distinctive character and thus remain unidentified except that they probably belong to the anomaly 5B-5A sequence." Menard[1] was apparently confident that anomaly 5B could be identified there but his interpretation has remained controversial. In our interpretation of the magnetic anomalies of the ares we rely on closely spaced east–west aero magnetic anomaly profiles[9] which are shown together with their original interpretation in Fig. 1. These data allow the anomalies in the unevenly preserved anomaly 5 series to be identified more confidently than before.

Taylor *et al.*[9] emphasized the variable seafloor spreading rates in the vicinity of Isla Guadalupe. In their interpretation, spreading rates decrease monotonically from the latitude of Isla Guadalupe northwards and increase southwards although remaining at uniformly lower rates than north of the island. Their suggestion that a fracture zone is present at about the latitude of Isla Guadalupe has been confirmed by seismic refraction work[12]. However, Taylor *et al.*[9] did not attempt a detailed reconstruction of the tectonic history of the area.

We have renumbered the magnetic anomalies of Taylor *et al.*[9] in accordance with a more recent magnetic time scale and anomaly nomenclature[13]. Figure 2 shows our new anomaly identifications which differ from those of Taylor *et al.*[9] (Fig. 1) by the addition of anomaly 5E and the shift of the rest of the anomaly 5 series. We have also reinterpreted some of the profiles south of Isla Guadalupe and have identified reversed anomalies 5B and 5C to the east of Guadalupe (Fig. 3). Finally, we have plotted the magnetic anomalies of Fig. 1 onto Taylor *et al.*'s[9] map of the area to show the geographical distribution of

Profile letters correspond to those of ref. 9, some of which are shown in Fig. 1. North, middle and south segments are shown in Fig. 4. Spreading rates were estimated by comparing data profiles with synthetic profiles of known spreading rate, therefore estimates of precision of these values are subjective, and are no better than ±1 mm yr^{-1}.

the magnetic anomalies (Fig. 4). Table 1 shows average spreading rates for various time intervals computed using Blakely's time scale for the Miocene[13].

Figure 4 indicates important aspects of the tectonic evolution of the area. First, we have detected a major offset in the anomaly 5 series north of Guadalupe (Fig. 4) which corresponds to a series of east–west ridges. The magnitudes of the offsets of anomalies 5E, 5D, and 5C increases monotonically as they do for the fracture zone at the latitude of Isla Guadalupe. Several smaller anomaly offsets may also exist in the region north of the island, but more closely spaced magnetic data will be needed to confirm their presence. Figure 4 represents the simplest possible anomaly pattern which can be derived from the data.

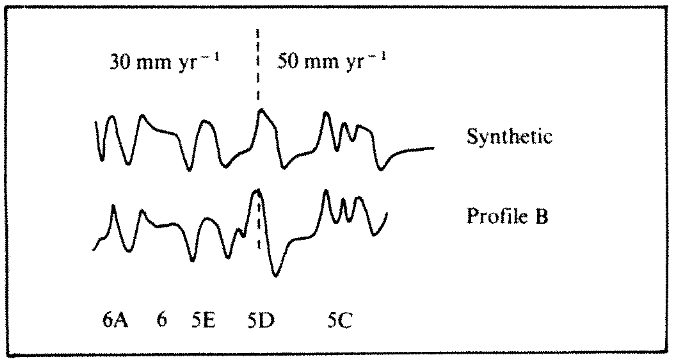

Fig. 2 Comparison of synthetic anomaly profile with data of profile B. Our new identifications are shown. Note variable spreading rate of synthetic profile.

The tectonic history of the region inferred from this pattern of anomalies is: (1) During anomaly 6A and 6 time (20–22.3 Myr BP) two segments of the Pacific–Farallon system offset by a transform fault at about the latitude of Isla Guadalupe were spreading at maximum rates of ~35 mm yr^{-1} (Table 1). The rates for the northern segment increase southwards producing fanning anomalies and an arcuate fracture zone. For this segment, rates increase from ~30 to 33 mm yr^{-1} in the south. Anomaly 6A shows little or no offset, but anomaly 6 is offset across the fracture zone; thus, either spreading was asymmetric or the northern and southern segments belonged to different plates. We prefer the first explanation.

(2) Between anomaly 5E and 5B (12.5–20 Myr BP) reorganization of spreading geometry resulted in formation of a third ridge segment north of Isla Guadalupe. This may have been caused by interaction of this portion of the Farallon plate with the continental margin of Baja California. Anomaly offsets across this transform fault–fracture zone increased monotonically with time and spreading rates were variable (Table 1). Spreading rates south of Isla Guadalupe increased to about 40 mm yr^{-1} as shown previously[9], but then slowed again to about 35 mm yr^{-1}.

(3) Just after anomaly 5B time (12.5 Myr BP) the southernmost segment of the Pacific–Farallon system in this area jumped to the east. This is inferred from the presence of anomalies 5B and 5C east of the Guadalupe trough, which we suggest is an extinct spreading centre. This series of discontinuous linear troughs (Fig. 4) extends from the southern tip of Isla Guadalupe to the Shirley Trough at about 27°N (J. Mammerickx, personal communication). Table 1 shows that during anomaly 5C and 5B time, spreading at the Guadalupe Trough was asymmetric: about 41 mm yr^{-1} on the west flank and 45 mm yr^{-1} on the east. This is why we favour asymmetric spreading over plate

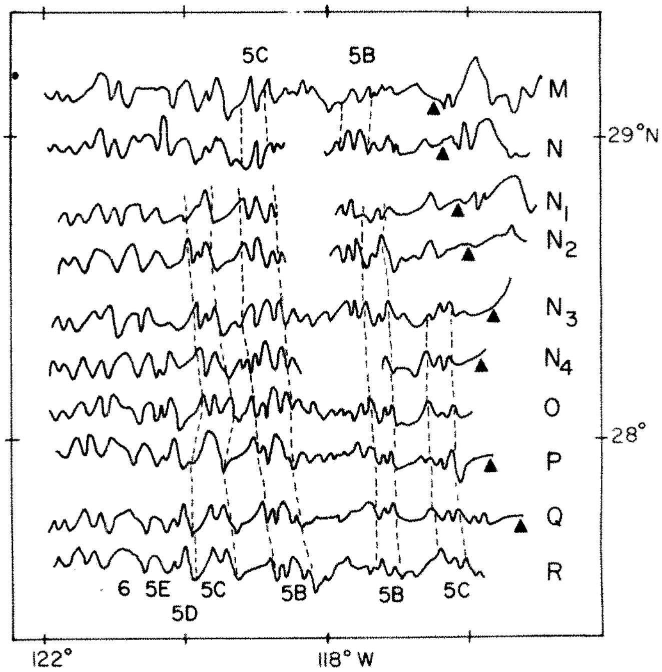

Fig. 3 Dashed lines show our new magnetic anomaly identifications and correlations for the southern part of the area which includes the Guadalupe Trough. ▲, Location of the 1,000-fathom bathymetric contour.

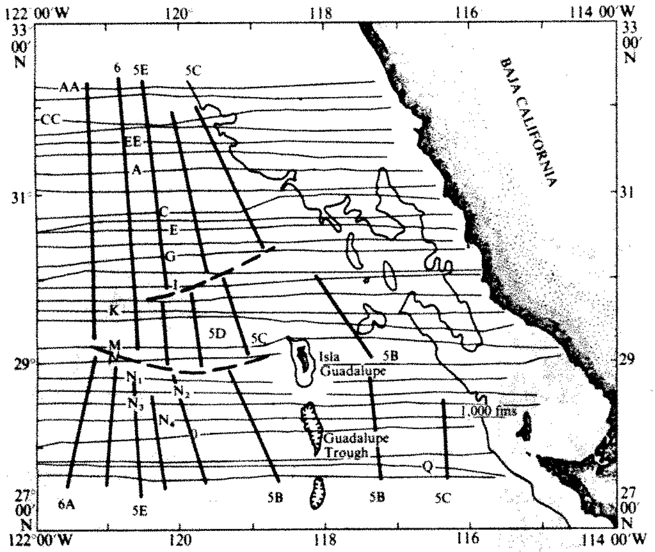

Fig. 4 Our new magnetic anomaly interpretations and the Guadalupe Trough[14] added to one of Taylor *et al.*'s maps.

fragmentation as an explanation for the smoothly increasing magnetic anomaly offsets on both transform fracture zone systems in the area.

To test our new magnetic anomaly interpretation east of Isla Guadalupe as well as the hypothesis of interrupted spreading (ridge jump), synthetic mangetic profiles for continuous versus interrupted spreading are compared with data of Taylor *et al.*[9] in Fig. 5. While neither synthetic is a perfect match to the data, the interrupted spreading model is certainly a better fit.

It is not known whether the ridge segments north of Guadalupe also jumped to the east at the time when the Guadalupe Trough became inactive because linear magnetic anomalies farther east have not been recognized. If Taylor *et al.*[9] are correct in their identification of anomaly 5 in profiles L, M and N then these segments probably continued to spread continuously (at least until 9 Myr BP). Alternatively, Taylor *et al.*'s[9] anomaly 5 could be 5A, or a buried basement ridge, or perhaps even another fossil ridge crest. In the former case, Isla Guadalupe occupies the intersection of a fracture zone and a fossil ridge, and is not simply built along a fossil ridge as previously proposed[14]. More detailed magnetic data will be required to determine the precise location of this fraction zone and thus the actual tectonic environment in which the Guadalupe volcanoes originated and evolved.

The spreading rate data of Table 1 give an insight into the possible relationships between the observed systematic changes of spreading rate before the ridge jump and the underlying causes of such jumps. As shown above, the ridge jump was probably preceeded by at least 10 Myr of asymmetric spreading in the entire region. Spreading rates increased from 30–33 to 40–50 mm yr^{-1} between anomaly 5E and 5D time (18–19 Myr) and remained high but variable until just before the ridge jump when spreading rates again slowed to ~34 mm yr^{-1}. While the underlying causes of such jumps are not yet well understood, clues to the mechanism for ridge jumps may be provided by detailed study of the spreading history of a ridge segment before episodic migration. In the case of the Guadalupe trough, the slower spreading, its asymmetry and the interaction between the farallon plate and the continental margin of Mexico may all have contributed to the ridge jump. Alternatively, the spreading history of the Guadalupe trough may reflect the action of different causes of ridge migration, for example, relative displacement between elements of mantle convention and the overlying lithosphere.

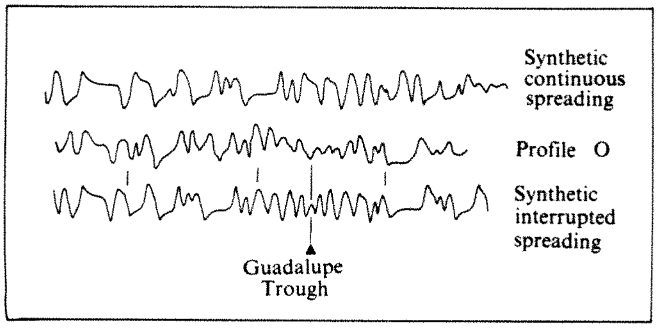

Fig. 5 Comparison of profile O data to both continuous and interrupted spreading synthetic anomaly profiles. The interrupted spreading synthetic is a composite of four profiles generated at various spreading rates (segments separated by short vertical lines above the profile). The spreading rates for these segments are: 30 mm yr^{-1} (west), 40 mm yr^{-1}, 33 mm yr^{-1} and 44 mm yr^{-1} (east). Although neither synthetic is a perfect match to the data, interrupted spreading is a much better fit.

We thank Patrick Taylor, Tanya Atwater and Richard Hey for discussions, and J. Mammerickx for an unpublished chart. This work was partly supported by NSF grant OCE-7727001 and an ONR grant to Rodey Batiza and an NSF grant to Chase.

Vertical distribution of mercury in sediments from the East Pacific Rise

Malcolm E. Cox & Gary M. McMurtry

Hawaii Institute of Geophysics, University of Hawaii, Honolulu, Hawaii 96822, USA

Concentrations of mercury are often high in waters and sediments associated with volcanic hydrothermal systems, in both marine and terrestrial environments. Whereas the concentration of mercury in open ocean waters is reported to be in the range 0.002–0.05 µg l^{-1} (refs 1–4), significantly higher values of up to 1.4 µg l^{-1} are reported in waters near, or having circulated through, areas of submarine hydrothermal activity[2,5]. Mercury concentrations of up to 400 p.p.b. (parts per 10^9) on a carbonate-free basis (CFB) have been measured in surface sediments on the East Pacific Rise crest, but concentrations decrease to <20 p.p.b. (CFB) on the peripheral seafloor[6]. Similar high concentrations from 160 to 890 p.p.b. (CFB) have been recorded in near-surface sediments from the median valley of the Mid-Atlantic Ridge[7]. We report here on the vertical variations of mercury in sediments from the East Pacific Rise, and suggest that increased concentrations are correlated with periods of increased submarine volcanic activity.

Detailed down-core mercury analyses were made at 10-cm intervals on three piston cores collected by the RV Kana Keoki in the vicinity of the East Pacific Rise. Two of the cores, KK71-PC85 and KK71-PC87, located within 40 km of each other, are from within 50 km of the palaeomagnetically defined spreading axis of the East Pacific Rise at 6° S latitude; the third, KK72-PC8, is from the adjacent Bauer Basin (Fig. 1). These analyses were conducted to observe what vertical variations may occur in mercury concentration in marine sediments, knowing

that (1) both terrestrial and submarine volcanism are episodic in nature; (2) temporal variations in bottom water mercury anomalies over spreading centres have been observed[8]; and (3) most published sediment mercury analyses are from the surface or near-surface.

Samples were immediately taken from the split core sections and were individually sealed in plastic vials before analysis on a Jerome Instrument Corporation model 301 gold film mercury detector. Weighed, air-dried samples were heated to >800 °C, and the mercury vapour released was transported by Hg-free carrier gas through various filters to remove water and acid vapours before adsorption onto the gold film. Changes in the resistance of the gold film due to mercury adsorption were monitored and calibrated by injections of standard amounts of

mercury saturated air[9]. The accuracy of the procedures was monitored with a soil standard (USGS geochemical exploration sample no. 5) of known mercury concentration. General lithogical descriptions, sedimentation rates and mean down-core chemical compositions based on samples taken at 50-cm intervals are presented along with the mean down-core mercury results in Table 1. Figure 2 shows plots of mercury concentration versus depth for the East Pacific Rise sediment cores.

The extreme vertical variations in mercury concentration in the East Pacific Rise sediments are significant, and may demonstrate episodic submarine volcanic activity. In agreement with previous work[7], the variations in mercury show little correlation to variations in other sediment components. By using an approximate sedimentation rate of 2 cm kyr^{-1}, and assuming that each major mercury peak represents an episode of significant submarine volcanic activity and that mercury concentrations are not appreciably affected by variable bottom-water movements, we can calculate mean recurrence intervals of the order of 25,000–35,000 yr for this region of the East Pacific Rise. These intervals agree within factors of two or three with periods separating major cycles of spreading activity (~10,000 yr) suggested from geological evidence for the FAMOUS area, the Galapagos Rift[10] and the East Pacific Rise at 21° N latitude[11]. However, this correlation further assumes that rise crest volcanic activity is confined to the spreading axis, and does not consider such activity or hydrothermal emission from nearby faults and seamounts (Fig. 1) which may complicate the observed vertical distribution of mercury. The lack of correspondence between major mercury peaks in the two cores and the generally higher concentration in core KK71-PC85, which is more distant from the spreading axis, suggest that the volcanic activity responsible for the mercury concentrations may be localized. More detailed sampling will be needed to establish the spatial and temporal relationship between volcanic activity and sediment mercury concentration. These measured variations in mercury concentration are also important in illustrating that surface values alone are not an adequate representation of the mercury concentration at a given location.

The absence of mercury in the Bauer Basin core agrees with previous surface work in this region[6]. Of the 42 analyses over the topmost 3.5 m of core KK72-PC8, only seven were above the 1 p.p.b. detection limit (Table 1). The basin is characterized by sediments rich in metals[12–14], and anomalously high heat flow has been measured there[15]. Various origins for the metals in these sediments have been proposed, including transport of hydrothermally-derived material into the basin from the adjacent East Pacific Rise[16], and hydrothermal activity within the Bauer Basin[14,15]. If a hydrothermal origin is feasible, then the fixation process for mercury in these sediments must be different from that for East Pacific Rise sediments. We propose that this difference results from a higher oxidation potential caused by the relatively lower sedimentation rates in the basin (Table 1 and ref. 17). About 80% of the inorganic mercury in oxic seawater will exist as the highly soluble HgCl$_4^{2-}$ form[18], whereas aqueous mercury will exist as the less soluble Hg^0 or HgS$_2^{2-}$ forms in less oxic waters[19,20]. This oxidation–reduction behaviour may also apply to organically complexed forms of mercury. Approximately 30% of the total aqueous mercury in seawater has been shown to associate with organic matter[21], and it is reasonable to assume that such associations will also occur in pelagic sediments. Preservation of organic matter in pelagic sediments is a function of the rate of oxidation, which is inversely related to the rate of sedimentation[22]. Similar oxidation–reduction behaviour has been proposed to explain the relative distributions of chromium[14] and of uranium[23] in the Bauer Basin and East Pacific Rise sediments.

We plan further work on submarine mercury distributions, and are currently investigating sediments from back-arc spreading centres and marine manganese deposits. On the Fiji Plateau, where mercury concentrations in surface sediments are

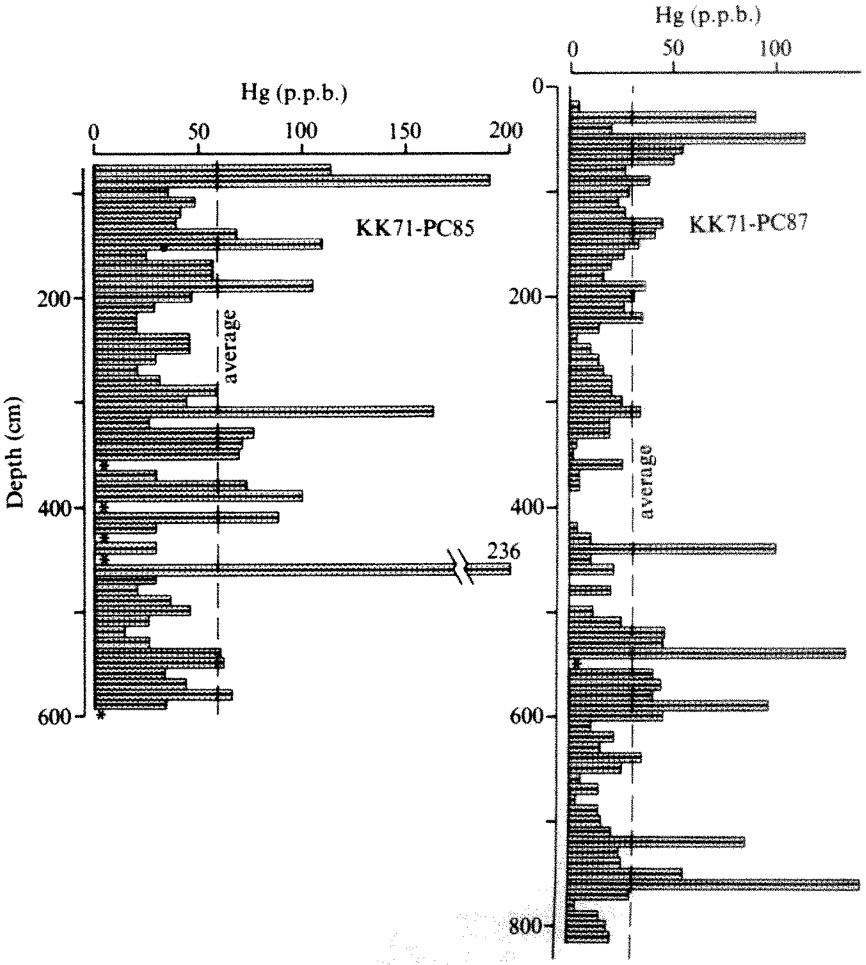

Fig. 2 Mercury concentration plotted against depth for the East Pacific Rise sediment cores. Because of coring disturbances, the topmost 70 cm of core KK71-PC85 was not analysed. generally low (<10–70 p.p.b.), the highest values correlate with increased heat flow[24]. Concentrations of mercury are extremely variable within marine manganese nodules (<1–810 p.p.b.), but are highest (>58 p.p.b.) in nodules from sea floor areas characterized by volcanic and hydrothermal features[25]. Similarly, mercury concentrations from several hundred to >2,000 p.p.b. were measured in ferromanganese crusts from active spreading centres[26].

Precambrian microfossils from the Sinian of South China

Zhang Zhongying*

Department of Geology, Nanjing University, Nanjing, China

The discovery of previously unknown microfossils from the Sinian of western Hubei Province, South China (Fig. 1) is reported here. The Sinian there, up to 1,000 m thick, is naturally divisible into four formations (Fig. 2) from the base upwards: (1) the Liantuo Formation comprising feldspar–quartz–sandstones with basal conglomerates; (2) the Nantuo Formation, which is a tillite; (3) the Doushantuo Formation, which has microdolomites intercalated with black shales and cherty beds with some siliceous or phosphatic nodules; and (4) the Dengying Formation, which is mainly dolomites. The rock sample in which the microfossils were found was collected from the lower part of the Doushantuo Formation near the highway side ~500 m east of Liantuo, Yichang County (Fig. 1). The Doushantuo Formation has been dated as 693±66 Myr (Rb–Sr isochron age)[1]. Pseudomorphs after gypsum sometimes occur in the lower part. The microfossils are preserved in siliceous nodules, particularly in the cherty portions. The dark colour of the nodules is due to the high organic content.

These new Doushantuo microfossils were discovered in petrographical thin sections and include at least four types—spheroids, colonies composed of unicells, nonseptate filaments and septate filaments. In some, fine structural details are well preserved, while others are modified or destroyed by diagenetic and subsequent processes. Figure 3 shows only a few of the new Doushantuo assemblage and a more detailed systematic account will be published elsewhere.

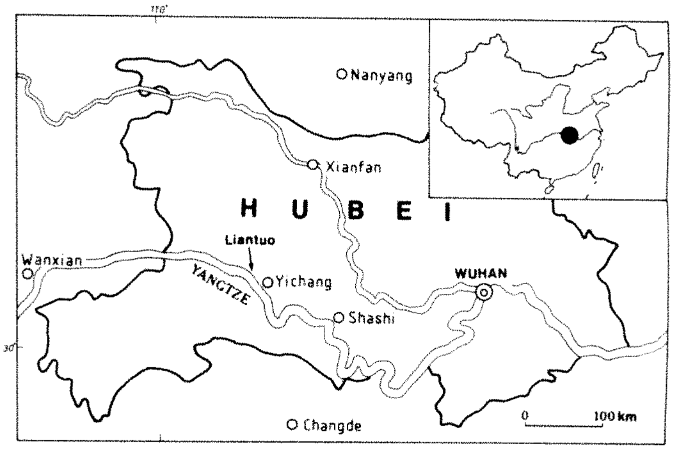

Fig. 1 Locality map.

Spheroidal members (Fig. 3*b–d*) of the assemblage range from ~8 to 18 μm in diameter, and exhibit granular or psilate surface textures. Although mainly solitary, and not associated with other organic matter, they are occasionally paired, or grouped in clusters. Some seem to contain inner dark spots ~2 μm across (Fig. 3*c*). In many colonies (Fig. 3*h*) where single spheroids 2–9 μm in diameter occur associated spheroids have also been found. Colonies may be up to >100 μm across, comprising a few to several tens of cells which set in a matrix of apparently mucilaginous material. Some of these colonies seem to have been disintegrated into smaller ones or into separate cells. These spheroids and colonies composed of unicells might represent chroococcacean cyanophytes, although some have uncertain affinities.

Both non-septate and septate filaments occur in the Doushantuo Formation, and some probable isolated trichomes and slime trails left by gliding filamentous algae or bacteria can be found. Organic walled non-septate filaments (Fig. 3 *e–g*) are generally straight or slightly sinuous, unbranched, 2–9 μm in diameter. Their maximum overall length is 56 μm. Occasionally loosely spirally twisted filaments have been found in petrographical thin sections. Variations in preservation may give these filaments a superficially septate appearance (Fig. 3*g*). Most of the non-septate filaments are interpreted to be discarded sheaths that originally enclosed cellular blue-green algal

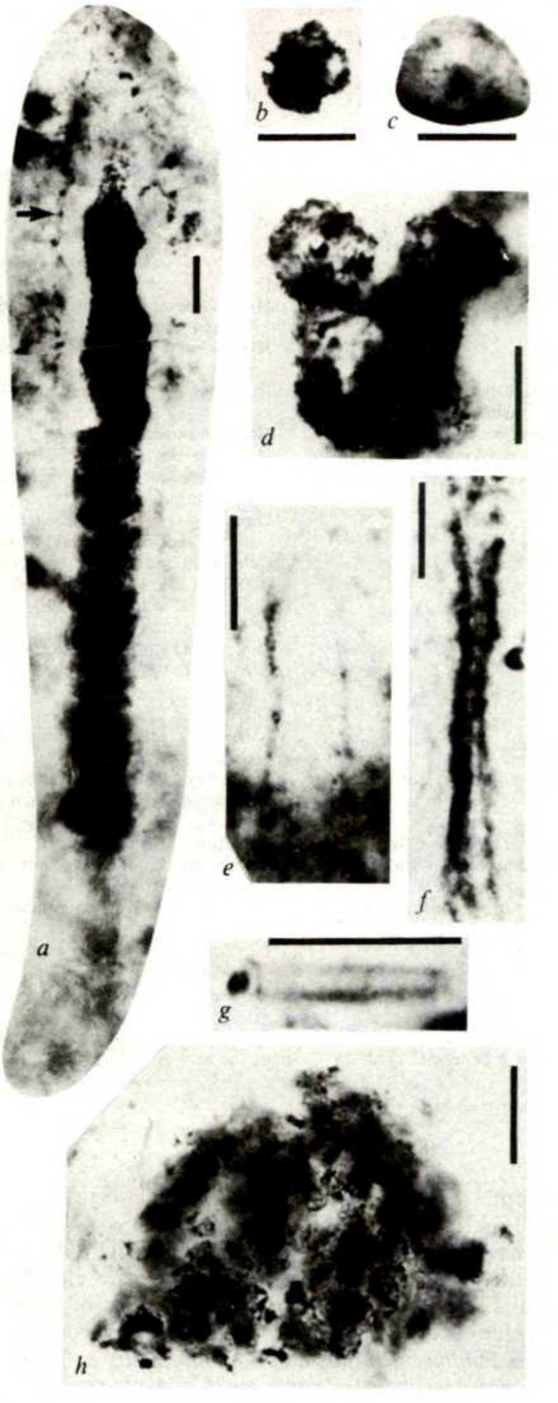

Fig. 3 Organically preserved microfossils from the Doushantuo Formation (late Sinian) of western Hubei Province, China. All micrographs are of petrographic thin sections in plane polarized light. *a*, A photomontage. Scale bars, 10 μm.

trichomes, while the narrower ones probably represent filamentous bacteria or oscillatoriacean algae.

Although septate filaments are rare and occur in a poor state of preservation, one nearly complete specimen (Fig. 3*a*) has been found. The filament is solitary and has a straight to slightly curved shape. The trichome composed of disk-shaped cells 9.0–11.0 μm in diameter and 3.5–5.5 μm in length is uniseriate, unbranched, not constricted or slightly constricted at septa and gradually tapering towards apices. The sheath (Fig. 3*a*, arrow) is hyaline, nonlamellated and up to 7.5 μm thick, gradually tapering towards apical portion. This specimen seems comparable with oscillatoriacean blue-green algae. Oscillatoriaceae-like filaments are very common and important among Precambrian microfossils, which have been found throughout the world[2-7]. The present form constitutes the first reliable record of them in the Precambrian rocks of China.

Sedimentological studies indicate that the Doushantuo Formation represents shallow water marine sediments formed in an arid climate[1]. The occurrence of the new Doushantuo assemblage predominantly composed of coccoid and filamentous cyanophycean algae supports this view. These microfossils seem comparable with some stromatolite-building organisms found in many Precambrian formations[2,5,8-11]. However, in China although rich microfossil assemblages and stromatolites have been described from Precambrian rocks, our knowledge about stromatolite-building organisms in these rocks remains very meagre, and few stromatolites from the Doushantuo Formation of South China have been reported[12]. On the other hand, this newly discovered microbiota represents one of the youngest Precambrian microfossil assemblages now known; others include those from the Vendian of South Kazakstan[10,13], the Arabian Shield[14] and the Lower Yudoma Suite[15].

I thank Professors J. Sutton and J. Watson for encouragement, Professor D. J. Shearman, Dr C. J. Peat and Dr W. L. Diver for valuable discussions, P. Grant, Huang Zhicheng and Ye Jun for rock identification, and Zhang Junming for collecting the rock sample.

Asymmetrical competition in insects

J. H. Lawton

Department of Biology, University of York, Heslington,
York YO1 5DD, UK

M. P. Hassell

Imperial College at Silwood Park, Ascot, Berks SL5 7PY, UK

It is widely believed that when populations of two species of animals compete, each has an adverse effect on the other[1,2]. In other words, each zero growth isocline ($dN_i/dt = 0$ where N_i is the population density of species i) is assumed to be some negative function of the population density of the other species. Cases where one species has a marked effect on the other, but there is no detectable reciprocal effect are sometimes distinguished as 'amensalism'[2,3]. This is regarded as unusual. Standard textbooks of ecology either do not mention it[1,4-6], define it but do not discuss it[2], or occasionally give a brief account[3]. Ricklefs[7] states that "competition can manifest itself by reducing the numbers of one or both competing species" without saying which is the more usual. Here we show that for insects in natural conditions, strongly asymmetrical competition (amensalism or near amensalism) is the norm rather than the exception by a ratio of at least 2:1.

Table 1 Examples of amensalism (strongly asymmetrical competition) between insect populations in the field

Ref.	Dominant (j)	Subordinate (i)	Mechanism	Taxonomic group, habitat and food
26	*Calliphora auger*	*Lucilia cuprina*	Resource exploitation and possible habitat modification	Diptera: sheep carrion
26	*Chrysomyia rufifacies*	*Lucilia cuprina*	Resource exploitation and aggression	Diptera: sheep carrion
28	'Early' Odonata	'Late' Odonata	Predation	Odonata: aquatic predators
30*	*Danaus plexippus*	*Oncopeltus* spp.	Extreme exploitation of food-plant	Lepidoptera and Hemiptera: milkweed plants
23	*Bombus pratorum*	*Bombus agrorum*	Aggression	Hymenoptera: artificial, experimental flowers
27†	*Sigara macropala*	*Hesperocorixa lobata*	Exploitation?	Hemiptera: aquatic detritivores
40	*Dacus dorsalis*	*Ceratitis capitata*	Larval interactions; mechanism?	Diptera: guave fruits
22	*Prenolepis imparis*	*Aphaenogaster rudis*	Aggression	Hymenoptera: experimental protein baits in woodland
41*	Several ant species	*Macromischoides aculeatus*	Aggression?	Hymenoptera: predators in cocoa plantations
42	*Fiorinia externa*	*Tsugaspidiotus tsugae*	Resource exploitation and action of shared parasitoid	Homoptera: eastern hemlock foliage
29	*Cromaphis juglandicola*	*Panaphis juglandis*	Habitat modification via excretion	Homoptera: walnut foliage
24	*Bombus terricola*	*Bombus ternarius*	Behavioural avoidance by subordinate	Hymenoptera: goldenrod flowers
25	'Mordellidae 23'	*Epiblema* sp.	Aggression and death of subordinate	Coleoptera and Lepidoptera: plant stems in prairie
43	*Copestylum* cf. *obscurior*	*Quichuana picadoi*	?	Diptera: water-filled *Heliconia* bracts: nectar, detritus and plant tissue
43	*Gillisius* sp.	*Beebeomyia* sp.	?	Coleoptera and Diptera: water-filled *Heliconia* bracts: plant tissue
43	*Gillisius* sp.	*Cephaloleia puncticollis*	?	Coleoptera: water-filled *Heliconia* bracts: plant tissue
43	*Merosargus* sp.	*Gillisius* sp.	?	Diptera and Coleoptera: water-filled *Heliconia* bracts: detritus and plant tissue
43†	*Quichuana picadoi*	*Gillisius* sp.	?	Diptera and Coleoptera: water-filled *Heliconia* bracts: detritus and plant tissue
44	*Copestylum roraima*	*Cephaloleia neglecta*	Disturbance and behavioural avoidance	Diptera and Coleoptera: water-filled *Heliconia* bracts: detritus and plant tissue
45	*Cephaloleia neglecta*	*Xenarescus monocerus*	Interference leading to emigration	Coleoptera: *Heliconia* bracts
18	*Urophora solstitialis*	*Rhinocyllus conicus*	Habitat modification via gall formation	Diptera and Coleoptera: plant tissue in flowerheads of thistle
18	*Larinus sturnus*	*Rhinocyllus conicus*	Probably exploitation of resources	Coleoptera: plant tissue in flowerheads of thistle
18	*Encosma* and *Homoeosomo*	All other species in flower heads	Aggression and predation	Lepidoptera and other: plant tissue in flowerheads of thistle

The dominant species, j, has a marked effect on the subordinate, i, ($\alpha_{ij} \gg 0$) whilst the reciprocal effect is negligible ($\alpha_{ji} \simeq 0$). Less certain, probably amensal, examples are marked *. There are two cases (†) in which the inferior species (i) seems to have a beneficial effect on j, moving the zero growth isocline of the latter clockwise, to intersect the N_1 axis of Fig. 1*b* at >90°.

The view that interspecific competition plays a key part in structuring guilds of birds and mammals is central to current thinking in community ecology[8,9]. Insects have been relatively neglected in this context, despite being the most important terrestrial, and amongst the most important freshwater, consumers. Insects have vastly more species[10] and frequently dominate terrestrial communities in terms of biomass and energy transfer. Widespread amensalism amongst insects would thus have important implications for theoretical community ecology.

Having reviewed the evidence for interspecific competition amonst insect populations in the field[11], we have found major and consistent differences between groups in the apparent importance of competition. Thus, whilst the ants and bees provide many good examples of competition, competition for food between phytophagous species is unusual[12]. Where species do compete, irrespective of their taxonomic group or the type of resource exploited, competition is generally highly asymmetrical. The 23 such examples that we have found are listed in Table 1; they probably provide a conservative total as some involve more than one pair of species. Only those cases where we can be reasonably certain of the degree of asymmetry in the interaction have been included. There are several other reports in which the effects of one species on another are clearly established, but the magnitude of the reciprocal interactions is not given, or cannot be deduced with any degree of certainty (see refs 13, 14 for example). Note that the criterion for amensalism is not simply that one species excludes another: this may happen when both α_{ij} and $\alpha_{ji} > 0$. Instead we require that $\alpha_{ij} > 0$ but $\alpha_{ji} \simeq 0$ (Fig. 1).

We have found only five reports of unequivocal, reciprocal competition involving insect populations in the field—four species-pairs and one larger group. Two species of leaf-feeding Homoptera in the genus *Eupteryx* compete reciprocally[15], as do the bees *Bombus appositus* and *Bombus flavifrons*[16], the aquatic Hemiptera *Arctocorisa carinata* and *Callicorixa producta*[17], and a pair of parasitic Hymenoptera in the genus *Eurytoma*[18]. In addition, McClure and Price[19] demonstrate competition in eight pair-wise experiments involving seven species of Homoptera all in the genus *Erythroneura.* If all eight pairs of interactions show statistically significant reciprocal effects (it is not clear from their data whether this is so), the ratio of examples showing amensalism (Table 1) to those showing more symmetrical competition is approximately 2:1 (23:12). If we choose to count the intensely studied genus *Erythroneura* only once, this ratio rises to nearly 5:1 (23:5). Whatever the exact ratio, the notion that amensalism is unusual is clearly not supported by the data: quite the reverse is true.

Obviously, the data must be interpreted carefully. We have probably overlooked some examples and may have misinterpreted others. Omission of uncertain but possibly symmetrical examples is balanced by cases where amensalism is probable but not proved[20]. Similarly, although there are cases of partial behavioural dominance, and hence possible reciprocal competition (for example, the ants *Pogonomyrmex rugosus* and *Pogonomyrmex desertorum*[21]), these are balanced by examples of almost certain total dominance (*Camponotus* ants frequently kill, maim and displace *Aphaenogaster* in confrontation at food sources[22]). Complete exclusion from preferred resources[22–24] undoubtedly affects colony dynamics in a highly asymmetrical manner. In brief, we think it unlikely that enough examples have been overlooked or misinterpreted to alter our conclusions significantly.

Given the difficulties in determining levels of competition in field conditions and the inevitable noise in the data, it is, of course, impossible to distinguish cases of true amensalism ($\alpha_{ij} > 0$; $\alpha_{ji} = 0$) from cases which are nearly so ($\alpha_{ji} \simeq 0$), and there is undoubtedly a continuum of examples from the truly symmetrical ($\alpha_{ij} \simeq \alpha_{ji} > 0$) to complete amensalism. However, the evidence suggests that examples are not uniformly distributed along this continuum. Strongly asymmetrical competition seems to be the general case, rather than the exception.

The examples of strongly asymmetrical competition summarized in Table 1 cover a wide range of feeding behaviour, including phytophages[25], carrion feeders[26], aquatic detritivores[27], predators[28] and nectivores[24]. They also arise in several very different ways, involving simple avoidance behaviour[24] of one species by another, direct aggression[22] (including, in extreme cases, the death of the inferior competitor[25]), habitat modification[29] or simple exploitation of resources[30]. In several cases the mechanism is not known with certainty; only its effect. The breadth of these examples, and the range of habitats and taxa involved, strengthen our belief that strongly asymmetrical competition is the norm in insects.

Strongly asymmetrical competition approaching amensalism has been widely reported in other groups of animals and, just as for insects, may well be much commoner in these than has generally been acknowledged. Examples include organisms as different as barnacles[31], hummingbirds[32], small mammals[33] and wildebeest and buffalo[34]. Morse[35] provides an extensive review of social dominance between animal species (mainly mammals, birds and fish, but also nine insect examples and one involving Crustacea). Interactions are usually high asymmetrical, particularly where the fundamental niche of an aggressively dominant species is 'included' within that of a subordinate species[35,36]. We emphasize, however, that our examples include several forms of competition, not just social dominance.

We expect the dynamics of species associations in which amensalism is the norm to be very different from those dominated by symmetrical interactions. For example, predictions about niche shifts[32], stability[37,38] and estimates of connectance[39] are all likely to be affected. We believe that studies of community organization for those groups of species in which competition is known to be important should now pay much more attention to highly asymmetrical interactions, treating amensalism as a common, widespread form of species interaction.

We thank J. D. Currey, M. C. Crawley, J. Soberon, J. Waage and M. H. Williamson for valuable comments on the manuscript.

Received 2 October, accepted 16 December 1980

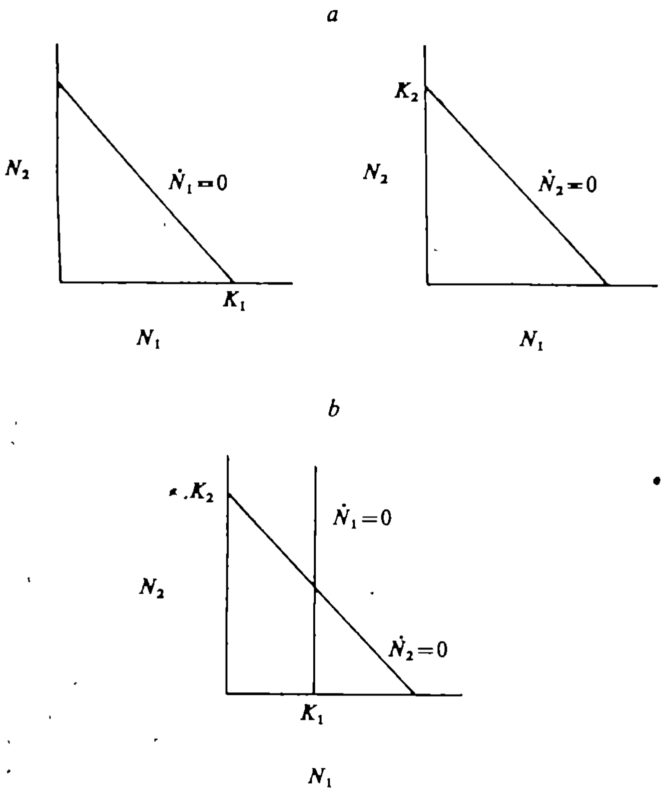

Fig. 1 *a*, Zero growth isoclines for the conventional two-species Lotka–Volterra competition model[1,3].

$$\frac{dN_1}{dt} = r_1N_1(1 - N_1/K_1 - \alpha_{12}N_2/K_1)$$

$$\frac{dN_2}{dt} = r_2N_2(1 - N_2/K_2 - \alpha_{21}N_1/K_2)$$

N refers to the population densities of species 1 and 2, *r* to their intrinsic rates of increase, *K* to their carrying capacities, and α_{12} and α_{21}, the competition coefficients, to the competitive effects of one species on the other. Stable coexistence or the exclusion of one species by another depends on the relative position of the two isoclines. *b*, With amensalism, the population of one species (species 2 in this example) is markedly affected by the other (that is, $\alpha_{21} > 0$), but the reciprocal effect is zero ($\alpha_{12} = 0$). If the isoclines intersect, as shown here, both species coexist. Otherwise the affected species (species 2) is inevitably excluded.

Time course of O^6-methylguanine removal from DNA of *N*-methyl-*N*-nitrosourea-treated human fibroblasts

A. S. C. Medcalf* & P. D. Lawley

Pollards Wood Research Station, Institute of Cancer Research,
Nightingales Lane, Chalfont St Giles,
Buckinghamshire HP8 4SP, UK

Methylating mutagens are thought to act by induction of direct miscoding, mainly through formation of O^6-methylguanine (O^6MeG) in DNA of, for example, T-even bacteriophage[1], *Escherichia coli*[2], and a cultured Chinese hamster cell line[3]. A positive correlation between this reaction in DNA of target tissues and subsequent induction of tumours has been found for rat kidney tumours[4] and thymic lymphomas in mice[5]. These effects are thought to be counteracted by an enzymatic repair process, which removes O^6-MeG from DNA (first found in *E. coli*[6], then in liver of rats[7] and mice[5]). The predominance of liver as the site of this action *in vivo* led to suggestions[7] that this could account for the relative lack of susceptibility of liver tissue to methylating carcinogens, and also that the enzyme involved might be inducible[8]. Evidence for the latter has been claimed for rat liver[9], but is most convincing in *E. coli*[10] where inhibition of this enzymatic action is achieved by treating cells with chloramphenicol before methylation[11], thus specifically inhibiting protein synthesis. As there is very limited removal of O^6-MeG from methylated cellular DNA, compared with that of 3-methyladenine (3-MeA, a suggested DNA template-inactivating base), it is thought that the former reaction is mediated by a protein which is consumed by the reaction[12]. There have been reports[13,14] that human cells also can remove O^6-MeG, but the data did not clarify the time- and dose-dependencies of the process. We report here more effective removal at lower extents of methylation, which suggests a nonlinear dose response to methylating mutagens and carcinogens for human cells. There were no significant deficiencies in methylpurine removal from DNA of patients with ataxia telangectasia (AT) or xeroderma pigmentosum (XP).

We used untransformed rather than transformed cells as the latter might be relatively deficient in DNA repair capability; density-inhibited cultures[15] were used as it was considered necessary to treat the different cell strains in identical conditions. This eliminated possible cell cycle effects and also DNA synthesis as complicating factors. The cells used were 1BR2, 2BI (radiation repair-proficient), AT3BI and XP12BE (radiation repair-deficient.)

Human fibroblasts were treated with the methylating carcinogen *N*-[^{14}C]methyl-*N*-nitrosourea (MNUA) at doses of ~0.1 mM and ~0.5 mM and the amounts of ^{14}C-methylated purines in cellular DNA were determined after various times of incubation. 3-MeA was rapidly removed from DNA at both doses with a half life of ~2 h; the half life of 7-MeG was ~30 h. These rates are much greater than for the spontaneous hydrolytic loss of these purines from DNA and therefore indicate enzymatic removal processes. The chemically stable O^6-MeG was also removed from DNA (possibly by demethylation as in *E. coli*[16]) but the kinetics differed from those for the other methylpurines—a rapid component was found early on which removed ~2–4 μmol O^6-MeG per mol DNA-P (~4–8 × 10^4 molecules per cell) in the first 1–2 h, then the rate decreased to about one-fifth of its initial value. At the lower doses of MNUA, 90% of the O^6-MeG was removed within 10 h, whereas at the higher dose level over half still remained. Regarding the hypothesis that O^6-MeG is a directly miscoding base, which causes mutation and tumour initiation if not removed before replication of methylated DNA templates, more effective removal at lower extents of methylation suggests a nonlinear dose response.

The results are summarized in Fig. 1 and Table 1, presented respectively as amounts of methylated bases per 10^6 DNA nucleotides, and as ratios of methylated bases at various incubation times after methylation. No corrections were required for dilution of bases by DNA synthesis, as there was no significant reduction of specific radioactivity of ^{3}H-thymidine pre-label in cellular DNA. Clearly the methylpurines examined were actively removed from DNA, 3-MeA and 7-MeG much more rapidly then occurs by spontaneous hydrolysis (half lives of ~30 and ~110 h respectively)[17].

Figure 1 shows that the time course of removal of each methylpurine from DNA had its own specific characteristics. 7-MeG declined with approximately first-order kinetics (linear semi-logarithmic plot) and with the same half life at both dose levels. 3-MeA was removed much more rapidly, with nonlinear kinetics, but again the efficiency of removal was independent of dose. However, O^6-MeG showed markedly nonlinear kinetics, and approximated to a two-component time course, with a higher efficiency of removal at the lower dose than at the higher.

This conclusion rests on the assumption that the initial extents of methylation of cellular DNA at the O-6 atom of guanine can be calculated as 0.11 times the extent of methylation at the N-7 atom, that is, they are identical to those found for methylation of DNA in the isolated state *in vitro*, or in cells which cannot remove this base[3]. These calculated values are indicated by arrows on the *y* axes of Fig. 1. The extrapolations of the approximately linear portions of the graphs for the higher doses (Figs 1*b*, *d*) to zero time are quite close to, but significantly lower than, these calculated values. The earliest time points for which analyses of DNA could be carried out were 1–2 h after addition of the methylating agent, to allow for completion of the methylation reaction (half life ~0.2 h) and collection of cells for DNA isolation.

During this time, as is evident from the time courses for removal of O^6-MeG (Fig. 1) ~2 μmol per mol DNA-P atoms (or DNA nucleotide units) were removed at the lower dose, and ~3–4 μmol per mol DNA-P at the higher dose—this represents a much higher proportion of the initial reaction at the lower (~3 μmol per mol DNA-P) than at the higher dose (15–20 μmol per mol DNA-P). It was calculated from the known DNA content of the cells (~2 × 10^{10} DNA-P) that this rapid initial component removed 4–8 × 10^4 molecules O^6-MeG per cell per h, or ~1,000 per cell per min.

The rate of removal then declined at both dose levels, the linear portion of the graphs at the higher dose showing a rate of ~200 molecules per cell per min. These kinetic characteristics could be considered to support the view[12] that the initial process is 'quasi-enzymic', that is, that the protein involved is consumed by the reaction, and is initially present in a limited amount.

In view of reports that in *E. coli* this enzyme (or quasi-enzyme) is inducible by pretreatment of cells with low doses of methylating agents[12], the question arises of whether the enzyme in human cells is similarly inducible. Evidence for this is not yet available, but the observed rapidity of the initial component reaction in the present work contraindicates its induction by the experimental treatment. This follows from the finding that removal of O^6-MeG can be at least as rapid in human cells as that of 3-MeA, whereas in *E. coli* removal of the latter, which is effected by a constitutive enzyme, is more rapid, and enzyme induction in mammalian cells is expected to be a much slower process than in bacteria[18]. It is possible that, due to low levels of methylating carcinogens in the diet (for example, dimethylnitrosamine in meat products[19]), the enzymatic activity in isolated cells could have been preinduced in the donors. It might be difficult to distinguish between such preinduced activity and constitutive activity, but the persistence of preinduced activity through many cell generations in culture seems improbable.

Values of extents of methylation of DNA were obtained as described in the legend to Fig. 1, and additional experiments have confirmed the results with 1BR2, AT3BI and XP12BE. Survivals were determined by collecting density-inhibited cultures by trypsinization, and plating appropriate numbers of cells to allow for colony growth at plating efficiencies of 10–40%, using feeder layers as described elsewhere[24]. Survival is colony-forming ability of treated cells divided by that of controls, only colonies with >50 cells being scored. Additional experiments (data not shown) were done to show that survival in all cases increased to almost 100% after ~40 h incubation in the density-inhibited state.

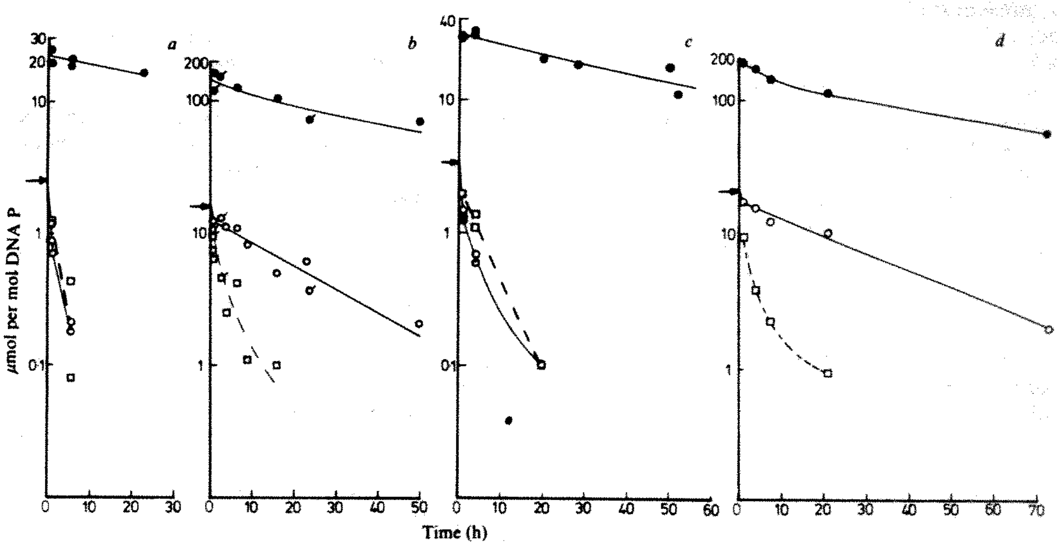

Fig. 1 These experiments were carried out in as near similar conditions as possible to eliminate the effects of variables such as DNA synthesis. The use of confluent cells was considered the most appropriate and convenient way of achieving this. Cells were obtained in this condition by a modification of the method of Weichselbaum *et al.*[15]. Cells (2×10^6) were inoculated into plastic tissue culture flasks (Nunc, 175 cm^2) containing Dulbecco's modified minimal essential medium (50 ml) supplemented with 15% fetal calf serum (Gibco). After incubation at 37 °C (48 h), ^3H-thymidine (Radiochemical Centre) was added (3 µCi $mmol^{-1}$, 7.4 µM), and the cells were collected after 24 h using trypsin/EDTA, pooled and the required number of flasks seeded with 2×10^6 cells in 50 ml medium; this ensures that there is equal specific radioactivity of ^3H-thymidine in each flask. There were only negligible decreases in the specific radioactivities of ^3H-thymidine in DNA over the experimental period, as expected for density-inhibited cells. The flasks were further incubated at 37 °C until confluence was reached, when the medium was collected for use as conditioned medium. This was repeated twice at daily intervals and the experiment was carried out 24 h after the last re-feed. Medium was removed from each flask, and the cells were washed once in prewarmed phosphate-buffered saline (PBS), residual PBS being removed by pipette. ^{14}C-MNUA (Radiochemical Centre, 37 mCi $mmol^{-1}$) was added to prewarmed PBS to give the required concentration for treatment, from a 1:200 volume of a stock solution in anhydrous dimethyl sulphoxide (DMSO), and 10 ml was added to each flask. The concentration was checked by assay of the radioactivity; controls were treated with DMSO (0.5% v/v). This concentration of DMSO was non-toxic and experiments with 1% (v/v) or no DMSO gave identical results. Treatment was for 40 min at 37 °C in the dark and was terminated by removal of radioactive PBS, and washing the cells once with warm PBS. At this stage and at appropriate times after incubation in conditioned medium, cells were collected from 1–4 flasks (dependent on the dose used). Sufficient cells were retained for assay of survival by the method of Cox and Masson[24]. The remaining cell residue ($0.3-1.5 \times 10^8$ cells) was used for isolation of DNA by a modification of the method of Kirby[25]. DNA (0.2–1 mg) was hydrolysed in 0.1 M HCl at 70 °C to liberate purine bases and analysed chromatographically using HPLC on a Partisil 10-SCX column eluted with a gradient of 0.05–0.4 M ammonium formate, 12–10% methanol, essentially as described by Frei *et al.*[5] Guanine and adenine were determined in each chromatogram by UV absorption of the appropriate fractions: ε_{max}(guanine) 8,000 at 273 nm; ε_{max}(adenine) 13,100 at 260 nm. The amount of DNA-P was then calculated as 2 × (mol guanine + mol adenine). This gave the extents of methylation of DNA, principally at O-6 and N-7 of guanine and N-3 of adenine. The initial extents of reaction at O-6 of guanine were calculated as 0.11 times the values for 7-MeG and are shown by arrows. *a*, 1BR2 treated with MNUA, (~0.1 mM); *b*, 1BR2 and 2BI (denoted by ○, □ and ●) treated with MNUA (~0.5 mM); *c*, AT3BI treated with MNUA (~0.1 mM); *d*, AT3BI treated with MNUA (~0.5 mM). ○, O^6-MeG; □, 3-MeA; ●, 7-MeG.

However, the slower component of the removal could be induced by the methylation damage to DNA.

Regarding a possible association between inherited defects in repair capability for radiation-induced damage in DNA and defective ability to remove methylpurines, our results showed no evidence for such an association in the AT or XP cells used. Previous reports[13,14] which claimed XP-associated defective repair of methylation damage were based on the use of virally transformed XP cells; therefore it cannot be ruled out that the defective removal of O^6-MeG was associated with the transformed nature of the cells, and not with any defect in UV repair capability.

Several implications for consideration of dose–response relationships in the associated mutagenic, transforming and tumour initiating effects of methylating carcinogens can be made from our results. Such relationships could explain why human cells have proved refractory to malignant transformation *in vitro* by such agents. One study[20] concluded that this transformation, by *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine required a relatively high degree of toxic action of the methylating agent, killing about 70% of the cells, that is, a correspondingly high extent of methylation of cellular DNA, possibly sufficient to reduce markedly the efficiency of O^6-MeG removal.

The levels of methylating carcinogens in the human diet are probably low[19] (for example, ~1–10 parts per 10^9 of dimethylnitrosamine (DMNA) was estimated in certain meat products) and it seems likely that these would lead to sufficiently low extents of DNA methylation to be removed very efficiently in cells with the same ability to carry out this reaction as the fibroblasts of the present study.

Analogous ability of cells of rat liver to remove this miscoding base from DNA, methylated by continuous feeding with DMNA, has been suggested[7] to account for the relatively low (or, on the concept that a no-effect threshold dose exists, zero) yields of induced liver cell cancer at lower dose levels (suggested threshold of 0.1 parts per 10^6)[21].

It is also relevant to consider the frequency of UV-induced mutation in human fibroblasts, which shows a no-effect threshold[22]. This threshold is associated both with efficient repair of UV-induced DNA damage, and with protection against the induction of mutation and cancer, because XP cells, deficient in this repair, show no threshold, and are more prone to the mutagenic and carcinogenic effect of UV light.

Another case of a markedly nonlinear dose response has been reported[23] for induction of mutation in human lymphoblasts by a methylating carcinogen, *N*-methyl-*N*-nitrosourethane, and this could also be ascribed to more efficient removal of the promutagenic base O^6-MeG at low doses.

Taken together, these considerations lead to the general hypothesis that cells with the ability to remove O^6-MeG from DNA more efficiently at lower extents of methylation, will show a markedly nonlinear dose response for malignant transformation by methylating carcinogens, with a very low probability per unit dose at low doses. In the present study the human cells examined were in this category and therefore should be correspondingly resistant to low doses of methylating carcinogens.

We thank Dr C. F. Arlett for supplying 1BR2 and 2BI cells, Professor D. G. Harnden for AT3BI cells, and Dr J. J. Roberts for XP12BE cells. This work was supported by grants from the CRC and MRC; A.S.C.M. was a postgraduate research student of the Institute of Cancer Research.

Distinct lung-colonizing and lung-metastasizing cell populations in B16 mouse melanoma

Christopher W. Stackpole*

Memorial Sloan-Kettering Cancer Center, Rye,
New York 10580, USA

Establishment of distant metastases by solid tumours requires that some tumour cells separate from the primary growth, infiltrate surrounding normal tissues, invade blood vessels or lymphatic channels, and extravasate into microenvironments favourable for proliferation[1]. It is probable that only a small subpopulation of tumour cells is endowed with these special attributes[2]. The biological properties of potentially metastatic tumour cells are being investigated extensively by means of an 'experimental metastasis' assay, in which cultured cells are introduced directly into blood vessels and, several weeks later, organs examined for tumour growths[1–8]. Although this assay allows controlled and quantitative experimentation, the suitability of experimental metastasis (colonization) as a valid representation of true metastasis is uncertain. I report here that organ colonization after injection of cells directly into the blood vasculature is not necessarily predictive of spontaneous metastatic potential from subcutaneous transplants. Indeed, some cell lines derived from the B16 mouse melanoma produce numerous lung colonies when injected intravenously (i.v.) but rarely metastasize, whereas others are spontaneously metastatic to the lungs but produce few lung colonies after i.v. injection. These differences in behaviour are evident only when the possibility of colonization occurring due to accidental introduction of melanoma cells into blood vessels is excluded.

B16 melanoma cell lines were maintained as monolayer cultures in 75 cm^2 plastic tissue culture flasks with Eagle's minimal essential medium containing 10% fetal bovine serum, 1.5% vitamins, 1% nonessential amino acids, 1 mM sodium pyruvate, 2 mM L-glutamine, 100 units ml^{-1} penicillin, and 100 $\mu g\,ml^{-1}$ streptomycin, *p*H 7.0. Primary lines were established from single-cell suspensions prepared from subcutaneous (s.c.) or intraperitoneal (i.p.) tumour transplants, lung colonies, or lung metastases, by mincing the tissue with scissors and pressing it through 80-mesh stainless-steel wire screens, and washing by low-speed centrifugation, in sterile conditions. Before experiments, monolayers were initiated from frozen stocks by seeding 5×10^4 viable cells and were collected ~24 h before confluence by incubation for 1 min at 37 °C with 1 ml of Hank's balanced salt solution, without calcium or magnesium, supplemented with 0.25% trypsin, 0.02% EDTA and penicillin–streptomycin. Single-cell suspensions free of cell clumps and >95% viable were washed twice with Earle's balanced salt solution containing 1% heparin and penicillin–streptomycin

Table 1 Lung colonization by B16-F10 cells injected at various anatomical sites

Injection site	No. of mice with lung colonies	Median no. of lung colonies
Lateral tail vein (i.v.)	20/20	88 (28–250)
Hind leg, footpad (i.m.)	7/20	6 (1–14)
External ear (i.d.)	3/20	12 (9–16)
Hind leg, thigh (s.c.)	5/20	5 (2–10)
Abdominal flank (s.c.)	0/20	0

Female mice 8–10 weeks old were partially immobilized by ether inhalation for 10 s, and 10^5 B16-F10 cultured cells in 0.05 ml of EBSS injected 5 mm proximal to the point of entry of a 27-gauge needle. Injections were into the lateral tail vein 2 cm from the base of the tail; into the middle of the hind foot 2–3 mm beneath the skin on the lower surface after insertion in the footpad; beneath the epidermis of the medial dorsal surface of the ear 5 mm from the ear base; beneath the skin on the ventral surface of the thigh midway between knee and hip; and beneath the skin midway between the front and hind legs 1 cm to the right of the abdomen centre. After 1 h, the injected areas were removed by amputation at least 5 mm proximal to the limit of the inoculum or by excision (flank), including a 5 mm margin beyond the inoculum boundary. Surgery was performed after anaesthetizing mice with chloral hydrate; large blood vessels were ligated and heat-cauterized, and open wounds were resealed with 9-mm stainless-steel wound clips. All mice were killed 21 days later and pigmented lung colonies counted by examining excised lungs with a dissecting microscope; complete autopsies revealed grossly visible tumour growth only in the lungs. These results were obtained in duplicate experiments carried out using 10 mice per group. Values in parentheses are the range of lung colonies in positive mice.

Table 2 Effect of surgical excision on metastasis of B16-F10 s.c. transplants

Procedure	No. of mice with lung nodules	Median no. of lung nodules
2.5×10^4–2.5×10^5 cells s.c. (autopsied at death 4–5 weeks later)	6/95*	8 (1–18)
2.5×10^5 cells s.c. ('careful' complete excision after 14 days; killed 6 weeks later)	1/20	4
2.5×10^5 cells s.c. ('careful' incomplete excision after 14 days; autopsied at death 4–6 weeks later)	11/18	66 (19–160)
2.5×10^5 cells s.c. ('careless' complete excision after 14 days; autopsied or killed 4–6 weeks later)	12/17	53 (5–165)

B16-F10 cultured cells in 0.2 ml of EBSS were injected s.c. in the right abdominal flank as described in Table 1 legend but mice were not anaesthetized before injection. Except as otherwise noted for the first group, mice were females 8–12-weeks old. 'Careful' complete excision was carried out as described in Table 1 legend and involved removal of all visible tumour plus a border of normal tissue at least 5 mm wide without disturbing the tumour; no local tumour growth occurred in any of these mice after excision. Incomplete excision was done in the same manner but only grossly visible tumour was removed; traces of tumour remained to grow and eventually kill all these mice. 'Careless' excision was done without ligating and cauterizing blood vessels, and tumours were handled without caution during removal; local tumour growth occurred in 53% of these mice. The mean size of excised tumours was 1.04 ± 0.45 cm^3, and all were richly vascularized. Values in parentheses are the range of lung nodules in positive mice.

* Included in this group were mice injected with 2.5×10^4 (0/15) and 2.5×10^5 (2/48) cultured cells, and 10^5 tumour cells purified from an i.p. transplant (1/10); male mice 8–12-weeks old injected with 2.5×10^5 cultured cells (1/10), and female mice 12–18-months old injected with 2.5×10^5 cultured cells (2/12).

(EBSS). Cell suspensions in EBSS were injected into disease-free C57BL/6 mice (Jackson Laboratory or our own colonies), matched in sex, age and weight for each experiment, within 10 min after collection[9]. Tumour cells from single-generation s.c. or i.p. transplants were purified to >90% viability and homogeneity by centrifugation on continuous-density gradients of buffered iso-osmotic metrizamide after physical separation of cells from solid tissue[10]. Tumour cells were prepared for injection in the same manner as cultured cells.

The B16-F10 cell line was highly selected by Fidler[3] to produce large numbers of lung colonies after i.v. injection, and s.c., intradermal (i.d.) and intramuscular (i.m.) transplants of these cells are reported to metastasize spontaneously to the lungs in 20–90% of syngeneic mice, usually after excision of the growing transplant[11–14]. With regard to metastatic activity, several of those transplantation sites are richly vascularized, and the possibility of introducing potential lung-colonizing cells directly into ruptured blood vessels during injection must be considered. When B16-F10 cells were introduced into various s.c., i.d. and i.m. sites and tumour prevented from developing at the injection site by amputation or excision of the affected areas, lung colonies developed in some mice (Table 1); in mice with growing transplants such colonies could be mistaken for spontaneous metastases. Only s.c. injection in the abdominal flank, in an area which was predetermined as relatively free of blood vessels visible at low magnification with a dissecting microscope, failed to result in some lung colonization, and this site was chosen for subsequent experiments. Similarly, surgical excision of B16-F10 transplants, while prolonging host survival and growth of pre-established micrometastases, could also allow tumour cells inadvertently to enter severed blood vessels and eventually colonize the lungs—this possibility was also examined. Tumours were excised with great care after 2 weeks of s.c. growth and lung nodules formed in <10% of mice, comparable with the incidence of nodules in mice bearing unexcised tumours (Table 2); these nodules may represent true spontaneous metastases. In contrast, careless or incomplete tumour excision resulted in extensive lung nodule formation, probably due to colonization rather than spontaneous metastasis.

With these considerations, lung colonizing and spontaneous metastatic capacities of a number of cell lines derived from the B16 melanoma were assessed. Each cell line was tested as cultured cells and as tumour cells, because the behaviour of cells growing in such diverse conditions might be different. The 'parent' B16 tumour, from which B16-LC (lung-colonizing) and B16-LM (lung-metastasizing) lines were derived, produced both lung colonies and metastases when tested as tumour cells, but cultured cells were nonmetastatic and only slightly active in colonization (Table 3). Ten B16-LC lines, of which B16-LC1 and B16-LC4 represent extremes in lung-colonizing capacities, and three lines selected by Fidler[3] and Hart[12] (B16-F1, B16-F10 and B16-BL6) were not significantly metastatic (0–20%) either as cultured or tumour cells. Clones isolated from lung-colonizing lines behaved similarly. In contrast, seven B16-LM lines were metastatic in 35–100% of mice. Lines derived from tumour transplants (B16-LM1, -LM2 and -LM3) were both colonizing and metastatic, although cultured B16-LM3 cells showed little activity in either assay (Table 3). Surprisingly, lines obtained from lung metastases (B16-LM4 and B16-LM6) were potently metastatic but at most only poorly colonizing. Twenty-five highly metastatic clones isolated from both types of metastatic line have also been tested—all were poor colonizers. A representative clone (C2) from the B16-LM4 line failed to colonize the lungs when 5×10^3 cultured cells were injected i.v. into five mice, produced few colonies (median 0, range 0–3, $n=5$) when 5×10^4 cells were injected, but formed numerous colonies (median 47, range 19–62, $n=5$) when 5×10^5 cells were injected. Paradoxically, it seems that cell populations that can spontaneously migrate to and grow in the lungs are less successful than many colonizing populations at proliferating in the lungs after direct i.v. introduction.

Table 3 Lung-colonizing and lung-metastasizing cell lines derived from the B16 melanoma

Cell line	Derivation	Growth form tested	No. of mice with lung colonies; median no. (range)	No. of mice with lung metastases; median no. (range)
B16	'Parent' tumour	C	10/10; 2(1–8)	0/10; 0
		T	10/10; 27(10–63)	4/10; 0(0–8)
Lung-colonizing lines				
B16-LC1	s.c. transplant (10)*	C	19/23; 1(0–7)	0/20; 0
		T	10/10; 30(12–66)	1/10; 0(0–3)
B16-LC4	Multiple lung colonies	C	10/10; 250(145–>300)	0/15; 0
		T	10/10; >300(74–>300)	1/10; 0(0–1)
B16-F1	(refs 1–3)	C	17/20; 11(0–25)	1/20; 0(0–1)
		T	10/10; 47(12–76)	0/10; 0
B16-F10	(refs 1–3)	C	25/25; 63(26–116)	1/25; 0(0–3)
		T	10/10; 180(91–>300)	1/10; 0(0–3)
B16-BL6	(refs 12, 14)	C	10/10; 37(16–68)	2/10; 0(0–4)
		T	9/9; 110(63–165)	2/10; 0(0–5)
Lung-metastasizing lines				
B16-LM1	s.c. transplant (18)	C	14/14; 16(4–61)	8/19; 0(0–4)
		T	20/20; 32(4–120)	16/18; 4(0–14)
B16-LM2	i.p. transplant (6)	C	20/20; 20(3–68)	9/24; 0(0–12)
		T	10/10; 75(35–146)	9/10; 6(0–19)
B16-LM3	s.c. transplant (23)	C	4/15; 0(0–6)	2/15; 0(0–1)
		T	14/20; 11(0–82)	14/20; 1(0–16)
B16-LM4	Single lung metastasis	C	5/30; 0(0–7)	26/29; 5(0–17)
		T	10/10; 3(1–15)	9/10; 4(0–26)
B16-LM6	Multiple lung metastases	C	9/20; 0(0–8)	16/19; 4(0–26)
		T	9/10; 4(0–13)	9/9; 4(1–35)

B16-LC and B16-LM lines were derived from transplants, lung colonies and lung metastases originating from the 'parent' B16 melanoma (tumour tissue that, except for brief periods of serial transplantation in syngeneic mice, had been stored frozen since 1962); these lines were tested within two passages after primary isolates were frozen. Other lines (provided by Dr Isaiah J. Fidler of the Frederick Cancer Research Center and by the Mason Research Institute) were also tested within two passages. Female mice 8–12-weeks old were used in all colonization and metastasis assays, which were carried out simultaneously for each cell line. Colonization was assessed by injecting 5×10^4 cells in 0.2 ml of EBSS into the tail vein, then counting lung colonies after 21 days; metastatic activity was determined by injecting 0.25 ml of EBSS containing 2.5×10^5 cultured cells, or 10^5 tumour cells, s.c. in the abdominal flank, then counting lung nodules after 4 weeks of undisturbed tumour growth. Local tumour growth occurred in all mice receiving s.c. injections. C, cultured cells; T, tumour cells.

* Transplant generations are indicated in parentheses.

These results indicate that, based on predominant behavioural characteristics, two distinct cell populations exist in the B16 melanoma: lung-colonizing and lung-metastasizing cells. There is no evidence from analysis of clones to indicate the existence of metastatic cells with potent colonizing abilities. However, the presence of a third population, consisting of noncolonizing nonmetastatic 'null' cells, is indicated by the relatively low activity of cultured B16, B16-LC1 and B16-LM3 cells in colonization and metastasis assays. The considerable behavioural differences between lines derived from the same tumour suggest that the relative proportion of colonizing, metastatic and 'null' populations in the B16 melanoma is highly variable and dependent on growth conditions. This tumour is thus even more heterogeneous and complex than previously thought[15], and the availability of cell lines and clones with such dramatical biological differences from a single tumour should facilitate efforts to elucidate the basis for metastasis.

This study was supported by the General Motors Surgical Research Laboratory of the Memorial Sloan-Kettering Cancer Center and by NIH grant CA-08748. I thank Patricia Stremmel for assistance.

Hypoblastic cells can form a disk inducing an embryonic axis in chick epiblast

E. Mitrani & H. Eyal-Giladi

Embryology Section, Department of Zoology,
The Hebrew University of Jerusalem, Jerusalem, Israel

The primitive streak of the chick embryo develops from one of the two layers of cells of the stage XIII blastoderm[1], the epiblast. The other layer of cells, the hypoblast, seems to be necessary for the induction of the primitive streak and also determines its orientation[2]—rotation of the hypoblast by 90° is followed by a similar rotation of the embryonic axis[3]. After stage XIII, the hypoblast is replaced by the invaginating endoderm and plays no further part in the development of the embryo[4]. By means of a technique for disaggregation and reconstituting cells of stage XIII hypoblasts, we have been able to show that the two functions, induction and orientation are independent and that, with reconstituted hypoblasts, the orientation of the primitive streak is determined by the epiblast.

It was not clear whether the hypoblast's function is just one of dictating the future polarity of the embryo or whether it also performs a specific inductive function. In normal development the hypoblast starts to appear at stage XI. It is formed by cells from two different sources: cells from the posterior part of the marginal zone[5] moving anteriorly, and polyinvaginating cells coming down from the central area of the one-layer blastoderm[1]. At stage XIII, if the fully formed hypoblast is removed, the remaining blastoderm can regenerate a new hypoblast, from the two above distinct sources, which is to generate axial development in the epiblast[6]. If the peripheral regions of the marginal zone and the area opaca are removed at stage XIII, the remaining part will include only the epiblast proper and the hypoblast. These two components are sufficient for development of normal embryos. If from such an operated blastoderm the hypoblast is also removed, the remaining epiblast proper will regenerate a second layer. However, although this layer will be formed in about the same time as when the marginal zone is present during regeneration, it will only be formed from polyinvaginating epiblastic cells and will not be capable of producing axial development in the epiblast. Only unorganized mesoderm such as blood islands will be formed[6]. It seemed possible that in the latter case, the information concerning direction of growth, which is normally transmitted by a normal hypoblast to the epiblast, is lacking, and therefore the epiblast fails to organize the resulting mesoderm in a polarized manner.

We have conceived a model system which allows us to separate induction from polarity within the hypoblast so that the two processes can be studied independently. For this purpose we use a culture system in which individual hypoblastic cells are made to grow and to aggregate into a disk which closely resembles the original hypoblast. This reaggregated hypoblast is then layered on to the ventral surface of a normal stage XIII epiblast and the system is incubated further on a chick vitelline membrane.

In some cases care was taken to mark, on the epiblast, the posterior side of the original blastoderm with carbon particles. The conditions used to obtain appropriate hypoblast aggregates varied. A compromise had to be reached between the minimum time necessary to obtain a proper aggregate and the time at which the functional capacity of the cells is maximal. The best hypoblast aggregates were obtained after culturing the hypoblastic cells for 11 h (Fig. 1*a*). If the hypoblastic cells were cultured for only 5 h the aggregates formed were more difficult to remove as an intact sheet but were as functional as those obtained after 11 h. The results of the experiments in which hypoblast aggregates were layered on to the ventral surface of stage XIII epiblasts are summarized in Table 1. When reconstituted hypoblasts reaggregated for 11 h and layered on top of stage XIII blastoderms deprived of their original hypoblast were incubated further, they were able to induce development of normal embryos. Subsequent experiments were performed by layering the reconstituted hypoblasts on top of stage XIII blastoderms previously deprived of the hypoblast, the marginal zone and the area opaca (Fig. 1*b*, *c*). This ensured that the embryos obtained were not a result of regeneration of a new hypoblast from the marginal zone[6].

In 10 of the experiments performed, the expected posterior side of the embryo was clearly marked in the epiblast. Of these 10, all developed an axis according to the previously marked direction. The degree of development in all the experiments recorded in Table 1 varied from a definite primitive streak to embryos with several pairs of somites.

Table 1 Development and orientation of embryos from epiblasts incubated with reaggregated hypoblasts

	No. of experiments	No. of blastoderms with embryonic axis	Deviation from original blastoderm axis
Epiblasts with marginal zone and area opaca	5	5 (2)	0° (2)
Epiblasts proper, no marginal zone and no area opaca	17	14 (8)	0° (8)

Numbers in parentheses indicate the number of cases in which the direction of the axis was recorded.

Clearly the position of the cells with respect to each other in the primary hypoblast is not critical in bringing about an embryonic axis in the epiblast. The fact that the embryos developed in accordance with the expected axis of the original blastoderm indicates the existence within the epiblast of sufficient information to determine the future direction of

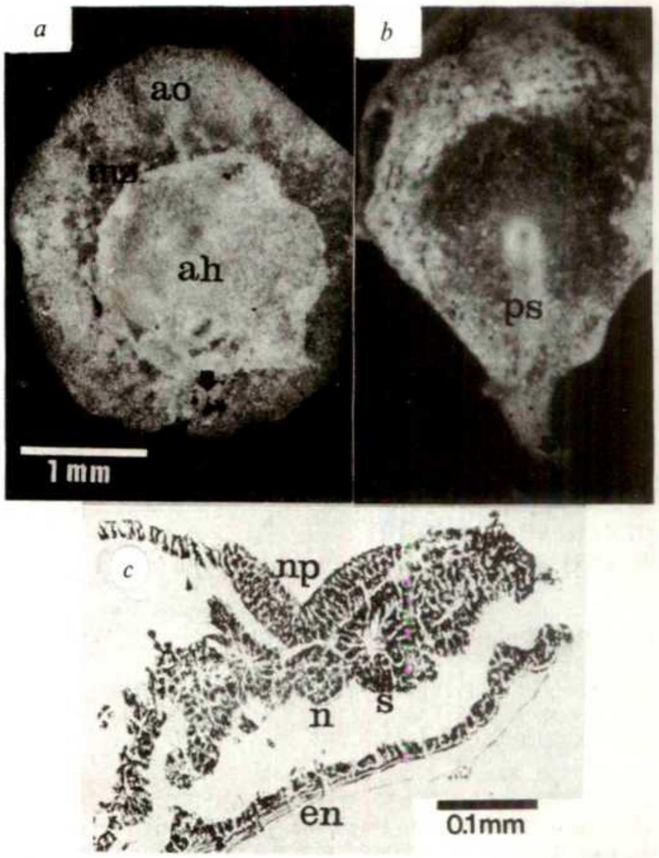

Fig. 1 *a*, The normal hypoblast has been replaced by the aggregated hypoblast (ah) in this stage XIII blastoderm. The marginal zone (mz) and the area opaca (ao) have been left to illustrate the relative area occupied by the aggregate. To prepare aggregated hypoblasts, normal hypoblasts were surgically removed from stage XIII blastoderms. To obtain individual hypoblastic cells, several hypoblasts were incubated in a solution containing trypsin and EDTA, transferred to the incubating medium, dissociated by gentle pipetting so that essentially a single-cell suspension was obtained, centrifuged down and resuspended in the incubating medium at a concentration of about 3×10^5 cells ml^{-1}. The incubating medium consisted of Dulbecco's modified Eagle's minimal essential medium containing 10% heat-inactivated horse serum. The cells were then incubated inside a hollow plastic cylinder whose internal diameter (3 mm) was slightly larger than that of an intact hypoblast. The cylinder of between 1 and 2 cm in height was made to stand on the lower side of a chick egg's vitelline membrane which had previously been stretched on a glass ring and suspended on chick egg albumin. The system was incubated at 37.5 °C in an atmosphere of 95% air/5% CO_2 for between 3 and 11 h. During this period the dissociated hypoblast cells within the cylinder reaggregate at the surface of the membrane and may form a one-layer disk which closely resembles the original hypoblast. The plastic cylinder was then removed, and the reconstituted hypoblast detached from the membrane with fine glass needles and layered on to the ventral side of a normal stage XIII epiblast. *b*, Primitive streak (ps) that developed by layering a reaggregated hypoblast on top of an epiblast proper, previously deprived of the marginal zone and the area opaca. The expected posterior side of the embryo was marked with carbon particles (arrow) on the epiblast before removal of the area opaca. *c*, Transverse section of an embryo that developed from an aggregated hypoblast layered on an epiblast proper. The area opaca and the marginal zone were removed before incubation. np, Neural plate; ch, notochord; s, somite; en, endoderm.

growth of the embryo. The necessity of the interaction with hypoblastic cells but not with the intact polar hypoblast indicates that a normal hypoblast is also acting as an inductor, and consequently that this induction process is indeed a specific function performed by the hypoblast.

The nature of the 'induction' process performed by a normal hypoblast is not yet known. It is unlikely, however, that the hypoblast's function is just one of a physical layer that provides some sort of cover to the denuded epiblast and/or provides non-specific anchorage or guidance for the movement of mesodermal cells. As mentioned above, even a closely associated layer, unless it contains the marginal zone-derived cells, is not sufficient to generate axial structures on a stage XIII chick epiblast.

We have therefore demonstrated that two processes which are independent of each other are necessary for the development of an embryonic axis: a determination of the direction of growth, and a specific induction process which is performed by the hypoblast on the epiblast. Although these two processes are normally both performed by the hypoblast, the second is specific to the hypoblast and can be fully operative even if information concerning the direction of growth is lacking within the hypoblast. We have also demonstrated that in fact there exists a latent information on direction of growth stored in the epiblast which can be expressed by exposing the epiblast to a non-polarized process of induction. The direction of growth information contained in the epiblast is not dominant and is generally overriden by the stronger polarizing effect of a normal hypoblast.

It has also been shown here that a stage XIII epiblast proper can provide sufficient information to organize its own development in a polarized manner. Yet the mesoderm that develops when an epiblast proper is incubated further in the absence of hypoblastic cells, derived from a normal hypoblast, fails to show an axial pattern. It thus seems that only a certain type of mesoderm can be organized in an axial manner and that as a result of the interaction of the epiblast with the hypoblastic cells this particular type of mesoderm emerges.

Generation of cytotoxic T-lymphocyte precursor cells in T-cell colonies grown *in vitro*

Lai-Ming Ching & Richard G. Miller

Department of Medical Biophysics, University of Toronto,
and the Ontario Cancer Institute, 500 Sherbourne Street,
Toronto, Ontario, Canada M4X 1K9

The role of the thymus in T-lymphocyte differentiation remains unclear. The demonstration[1,2] that the thymus can restrict the T-lymphocyte specificity repertoire suggests that T cells acquire specificity within the thymus. However, the demonstrations of immunocompetent helper T cells[3] and cytotoxic T-lymphocyte precursor cells (CLPs)[4] in athymic nude mice suggest that the acquisition of some T-cell reactivity may occur without the thymus. We have been using T-cell colonies grown *in vitro* as a model system for studying various aspects of T-cell differentiation in both mouse[5–8] and man[9]. In one study[6] we showed that CLPs can be found in T-cell colonies grown from spleen cells of normal mice, each colony containing CLPs of several different specificities. The colonies containing CLPs are not clonal, appearing to have a colony-forming unit (CFU-T) of two (perhaps three) cells[6]. Here we provide direct evidence that the CLPs are spontaneously produced in the colonies. In addition, the cells of the CFU-T were characterized with antisera directed against the cell-surface marker Thy-1, which is present on all murine T cells, and the cell-surface markers Lyt-1 and Lyt-2, which are differentially distributed on different T-cell subclasses[10,11]. We found that the CFU-T contains both a Thy-1$^+$ and a Thy-1$^-$ cell, neither of which seems to carry either Lyt-1 or Lyt-2 surface markers.

T-cell colonies were grown from mouse spleen cells as described in Table 1, picked individually after 5–6 days of culture when they had reached a size of 3,000–5,000 cells, and transferred individually into microcultures where they were tested for their ability to generate cytotoxic T lymphocytes (CL) from CLPs. In the experiment shown in Fig. 1, colonies were grown from aliquots of a spleen-cell suspension which either had or had not been depleted of Lyt-2$^+$ cells. As both CL and CLPs are known[10] to carry the surface marker Lyt-2, depletion of Lyt-2$^+$ cells ensured that any CLPs detected in the colonies actually developed there. Both sets of colonies contained CLPs in that, after activation with the mitogen concanavalin A (Con A), they developed cytotoxic activity which could be removed by depletion of Thy-1$^+$ cells. The Thy-1 marker is found on all CL but is absent or only weakly present on a fraction of other types of cytotoxic effector cells[12]. Figure 1*b* shows that when aliquots of the spleen cells used to grow the colonies were tested in a mixed lymphocyte reaction, those depleted of Lyt-2$^+$ cells failed to develop cytotoxic activity, verifying that the depletion treatment did in fact remove CLPs.

Table 1 summarizes experiments designed to test the cellular composition of the CFU-T required for CLP generation. Spleen cells were treated as indicated and then tested for their ability to produce T-cell colonies. If T-cell colonies were obtained, they were individually tested for CLP content as in Fig. 1. Spleen cells, whether depleted of Lyt-1 cells, Lyt-2 cells, both Lyt-1 and Lyt-2 cells, or nylon wool-adherent cells, grew comparable numbers of T-cell colonies of which a comparable fraction contained CLPs. The number of CLPs per colony did not vary appreciably from group to group. Removal of all Thy-1$^+$ cells, however, had a different effect. Although comparable numbers of colonies were obtained, far fewer of them contained CLPs. These colonies were still T-cell colonies in that the cells were killed with anti Thy-1 plus complement (C′). The Thy-1$^+$ cell had to be viable and able to proliferate as the addition of either irradiated or mitomycin C-treated spleen cells to spleen cells depleted of Thy-1$^+$ cells did not increase the CLP content of the colonies. We have shown previously[6] using stimulator cells for activation of specific CLPs in normal spleen colonies rather than Con A activation of all CLPs, that each colony contains CLPs of 10 or more different specificities. These results have been confirmed[13] in experiments in which CLPs were activated using Con A but only CL specific for a particular target were measured.

The above data are consistent with the following model. The central component of the CFU-T is a Thy-1$^-$, Lyt-1$^-$, Lyt-2$^-$ cell which can give rise to Thy-1$^+$ cells in a colony. If the CFU-T also includes a Thy-1$^+$ but Lyt-1$^-$, Lyt-2$^-$ cell, CLPs are also generated in the colony. Although this latter cell seems to have an unusual marker distribution, such a distribution has been previously reported[14]. It is necessary to add the qualification that cells found to lack a marker in a complement-mediated cytotoxicity test may still have this marker but either at a low level or displayed in a manner such that complement-mediated lysis cannot occur[11].

A crucial unresolved question is the role of the thymus in generating the cells required for the CFU-T. Previous studies have shown that colonies containing Thy-1$^+$ cells can be grown

Table 1 Cellular composition of CFU-T for CLP generation

Cells plated	Colonies per 5×10^5 cells plated	% Colony cells killed by anti-Thy-1 and C′	Colonies with CLPs / Total colonies %
Spleen	27 ± 10	88	432/564 (77)
Nylon wool non-adherent spleen	68 ± 21	N.D.	84/96 (88)
Lyt-1 depleted spleen	22 ± 8	100	17/24 (71)
Lyt-2 depleted spleen	29 ± 11	85	67/83 (81)
Lyt-1 and Lyt-2 depleted spleen	21 ± 6	N.D.	12/12 (100)
Thy-1 depleted spleen	59 ± 26	98	6/238 (2.5)
Thy-1 depleted spleen plus mitomycin C-treated spleen	42 ± 10	N.D.	1/47 (2.1)
Thy-1 depleted spleen plus irradiated spleen	77 ± 27	N.D.	1/47 (2.1)

Colonies were grown by culturing 5×10^5 viable cells from RNC-*nu*/+ mice treated as indicated, in 1 ml of α-medium[23] supplemented with 0.8% methylcellulose, 40% PHA-LCM, 20% fetal calf serum, 5×10^{-5} M 2-mercaptoethanol and 0.3 mg ml^{-1} L-glutamine as previously described[6]. The PHA-LCM is conditioned medium prepared by incubating human peripheral blood leukocytes (10^6 cells ml^{-1}) for 7 d in α-medium containing 1% PHA and 10% fetal calf serum[16]. Colonies were tested for CLP content as indicated in Fig. 1 except that in some experiments 2×10^5 irradiated (1,500 rads) RNC-*nu*/+ spleen cells were used in place of RNC.*nu* spleen cells and that the cultures were not always supplemented with Con A conditioned medium, in which case peak response was on day 4 and cytotoxic activity per positive colony only half as great. All procedures gave equivalent results with respect to the fraction of colonies containing CLPs[13]. Nylon wool-adherent cells were removed by the procedure of Julius *et al.*[24]. Antiserum treatments on spleen cells were as in Fig. 1. The antisera used, with the addition of hybridoma anti-Lyt-1, clone W3, were also as in Fig. 1. Cells (10^7 per ml) were treated with mitomycin C (25 µg ml^{-1} in medium) by incubation for 20 min at 37 °C. Treatment of colony cells with anti-Thy-1 and C′ was carried out by incubating 10^5 pooled colony cells with anti-Thy-1 (1 : 50 final dilution) and rabbit complement (1 : 15 final dilution) for 45 min at 37 °C. Cell viability was assessed by eosin exclusion.

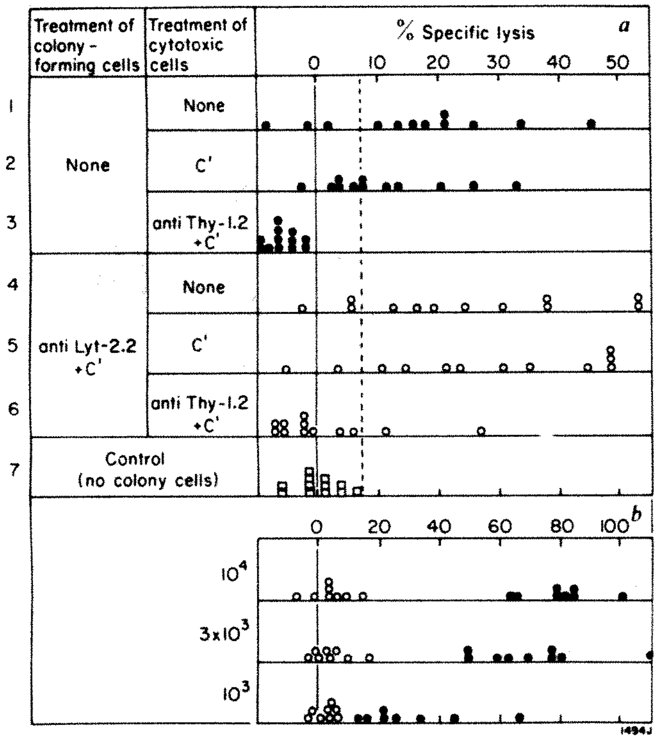

Fig. 1 *a*, Spleen colonies were grown from RNC *nu*/+ spleen cells which either had (○) or had not (●) been treated with anti-Lyt-2 plus complement and were then tested for their ability to produce CL from CLPs by transferring them individually into microwells along with 2×10^5 RNC. *nu* spleen cells in 0.2 ml of α-medium containing 2 µg ml^{-1} Con A and supplemented with 10% fetal calf serum, 5×10^{-5} M 2-mercaptoethanol and 10 mM HEPES buffer as described previously[6]. The mitogen Con A activates all CLPs regardless of specificity[25]. On day 3, 0.1 ml from each culture was replaced with 0.1 ml of conditioned medium from mouse spleen cells stimulated for 18 h with 5 µg ml^{-1} Con A[18] and on day 5, cultures were assayed for cytotoxic activity by adding ^{51}Cr-labelled DBA/2 splenic Con A blasts in the presence of PHA (final dilution 1:60) as described previously[6]. The PHA seems to stick CLs to target cells so that a CL can kill any target cell irrespective of whether it can recognize it[25]. Depletion of Lyt-2 cells was done by incubating 10^7 spleen cells with 50 µl anti-Lyt-2 hybridoma anitserum (clone 19-178) in a total volume of 0.5 ml medium at 4 °C for 30 min, followed by a wash and 45 min incubation at 37 °C with 0.5 ml rabbit complement (1:15 dilution) (Cedarlane Laboratory). Treatment with anti-Thy-1 was done by adding anti-Thy-1 antiserum (1:50 final dilution) and rabbit complement (1:15 final dilution) to the cultures for 45 min at 37 °C. Cultures were washed four times before the addition of ^{51}Cr-labelled target cells. Purified rabbit anti mouse Thy-1 glycoprotein antibody was used[26]. *b*, Three concentrations of the spleen cells used to grow the colonies tested in *a*, both untreated (●) and anti-Lyt-2 plus complement treated (○), were cultured with 3×10^5 irradiated (1,500 rad) DBA/2 spleen stimulators and 10^5 RNC. *nu* spleen cells and assayed on day 5 for cytotoxicity against DBA/2 splenic Con A blasts.

from Thy-1$^-$, presumably pre-thymic, progenitor cells in nude spleen[5], bone marrow[8] and long-term bone marrow cultures[7]. All these colonies seem to contain T-helper cell activity and those of bone marrow origin also contain Thy-1$^+$ cells which are apparently involved in inactivating certain self-reactive CLPs[8]. In common with colonies grown from normal spleen cells depleted of Thy-1$^+$ cells, none of these colonies contains CLPs. We hypothesize that the Thy-1$^+$ component of the CFU-T from normal spleen required to generate CLPs in colonies is a post-thymic cell. It might provide an equivalent to the thymus microenvironment required for CLP generation or itself be a post-thymic CLP precursor cell. According to Stutman[15], immunologically incompetent thymus-processed precursor cells are exported from the thymus to the periphery. The maturation of these post-thymic precursors into competent T cells requires specific interaction with inducer cells in the periphery. Thus, the CFU-T may represent the inducer, post-thymic precursor cell pair.

Growth of the T-cell colonies discussed here has an absolute requirement for a phytohaemagglutinin (PHA)-induced supernatant factor which we call PHA-LCM (see Table 1 legend, refs 16, 17). Although made in much the same manner as IL-2 (also called co-stimulator or T-cell growth factor (TCGF)[18–21]), the incubation period is much longer (7 days compared with 18–48 h). Neither IL-2 nor PHA alone will support growth of T-cell colonies of the type described here[22]. Thus, there seems to be factor(s) in the PHA-LCM which allows the *in vitro* growth and differentiation of more immature T cells than those T cells which can respond in the mixed lymphocyte reaction or can be made to grow in the presence of IL-2. Although the development of functional T cells in the colonies is certainly extra-thymic, this development should probably not be considered as thymus independent, even for those types of colonies for which the CFU-T contains no Thy-1$^+$ cells: the production of PHA-LCM is very likely to depend on the presence of T cells. We conclude that the T-cell colonies described here provide a valuable *in vitro* model system for investigating questions concerning T-cell differentiation and development of the CLP specificity repertoire not approachable with other available *in vitro* techniques.

We thank Dr G. B. Price for discussion and critical comments as well as for providing the PHA-LCM, Dr U. Hämmerling for providing the anti-Lyt-1 and anti-Lyt-2 antisera, and Dr M. Letarte for providing the anti-Thy-1 antiserum. This work was supported by the NCI of Canada.

Induction of light chain expression in a pre-B cell line by fusion to myeloma cells

Sylvia C. Riley, Emily J. Brock & W. Michael Kuehl

Department of Microbiology, University of Virginia, School of Medicine, Charlottesville, Virginia 22908, USA

Pre-B cells, the first cells in the B-lymphocyte differentiation pathway which express immunoglobulin[1], have recently been shown to express cytoplasmic μ heavy chain (H) but not light chain (L)[2,3]. If, as is believed, pre-B cells are the precursors of immature B lymphocytes, which express surface IgM[4–7], the differentiation of pre-B cells to immature B lymphocytes must be accompanied by the expression of light chains. In this case, it should be possible for the progeny of a single pre-B cell to express a variety of light chains in association with the same heavy chain. We have tested this hypothesis by hybridizing a pre-B cell line 18–81 expressing only cytoplasmic μ chains[8] with variant myeloma cells which do not express light chains. Hybridization of B-lymphoma cells with myeloma cells usually produces a hybrid with the phenotype of the more differentiated parent[9–11]. In this case, the fusion resulted in the induction of light chain expression from the 18–81 genes and we have been able to demonstrate that independent hybrids express different light chains, in accordance with the hypothesis that a pre-B cell committed to expression of a single μ heavy chain can generate progeny expressing different light chains[2,12].

We used a cloned, virus-transformed pre-B-cell line (18–81) which has been shown to express cytoplasmic μ heavy chain (μ_c) but no light chain. Our subline of 18–81 synthesizes up to 1% of its cell protein as μ_c in the absence of detectable light chain synthesis. A hypoxanthine guanine phosphoribosyl transferase (HGPRT)-negative clone of 18–81, 18–81.T5 (μ_c^+, L$^-$), was isolated and hybridized to CBOHC ($\gamma2_a^+$, L$^-$), a thymidine kinase(TK)-negative variant of myeloma CBO($\gamma2_a^+$, κ^+) which, like 18.81.T5, does not express light chain. Immunoglobulin expression was analysed by SDS-polyacrylamide gel electrophoresis of immunoprecipitates isolated from ^{35}S-Met-radiolabelled postnuclear supernatants. Immunoglobulin is expressed by 75% of presumptive hybrids; the reason for lack of immunoglobulin expression by hybrids is unclear but could be due to chromosome segregation. All immunoglobulin-expressing hybrids examined synthesize either or both of the μ and $\gamma2_a$ heavy chains of the parent cells and 13 (40%) of these express a κ light chain which is not produced by either of the parent cells (Fig. 1). Expression of λ light chain is not detected in these hybrids[13]. We tested for λ expression using rabbit antisera specific for mouse λI light chain. The hybrids were not tested for λII or λIII subclasses. To show that expression of κ light chain by these hybrids is not due to re-expression of the wild-type CBO κ light-chain gene, the CBO and hybrid light chains were analysed on an isoelectric focusing gel (Fig. 2). Light chains from three different CBOHC × 18–81.T5 hybrids (Fig. 2, lanes *c–e*) focused at a different *p*H range than the light chain from CBO (Fig. 2*f*). In addition, Southern blots of CBO and CBOHC DNA indicate that the expressed CBO κ light chain gene is deleted from the CBOHC variant (M. Kuehl, unpublished result). Thus expression of κ light chain by these hybrids is not due to re-expression of the wild-type CBO myeloma κ light-chain gene. It must therefore be due to expression of another myeloma κ light-chain gene or a pre-B cell κ light-chain gene. To determine whether the κ light chain expressed in pre-B cell × myeloma hybrids is coded for by the pre-B cell genome, a TK-negative clone of 18–81, 18–81.B4 (μ_c^+, L$^-$), was isolated and hybridized to NT$_2$(H$^-$, L$^-$, F$_{CL}^+$), an HGPRT-negative mutant of myeloma variant NP$_2$ which does not express heavy or light chains[14]. NT$_2$ contains only the aberrantly rearranged κ constant region (C$_\kappa$) gene which is expressed as a 12,000-molecular weight (MW) κ

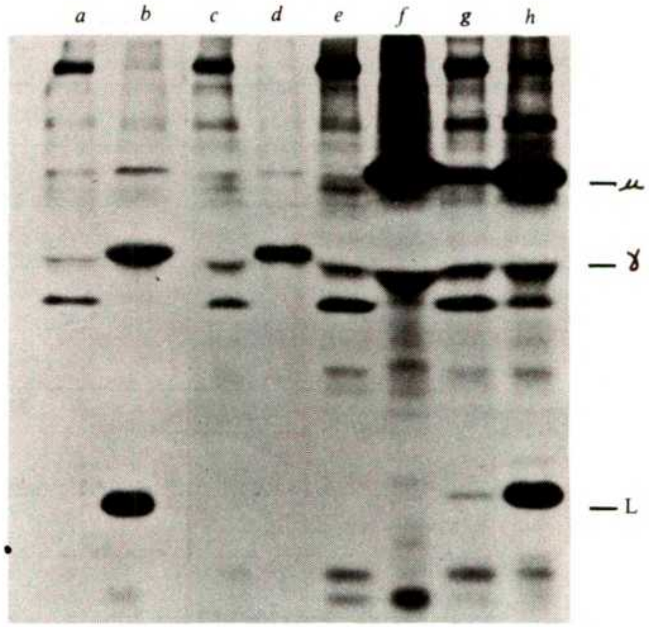

Fig. 1 SDS-polyacrylamide gel electrophoretic analysis of immunoglobulin synthesized by CBOHC myeloma, 18–81.T5 pre-B cell and CBOHC × 18–81.T5 hybrids. The 18–81.T5 HGPRT-negative variant of 18–81 was selected in 6 μg ml^{-1} 2-amino-6-mercaptopurine (6-TG). The CBO ($\gamma2_a^+$, κ^+) TK-negative variant of C1.3 was selected in 30 μg ml^{-1} 5-bromo-2′-deoxyuridine (BUdR) after mutagenesis with 1 μg ml^{-1} *N*-methyl-*N*′-nitro-*N*-nitrosoguanidine. The CBOHC ($\gamma2_a^+$, L$^-$) variant clone was isolated from CBO. 18–81.T5 and CBOHC were fused using 35% polyethelene glycol (PEG) by methods described by Gefter *et al.*[20] and modified by Clafin *et al.*[21]. The parent cells were washed free of serum and mixed in equal numbers (10^7 of each) in 35% PEG. The cells were pelleted twice by low-speed centrifugation, resuspended in growth medium plus HAT (hypoxanthine, aminopterin and thymidine), and cloned into 96-well microtitre plates. The cells and hybrid clones were metabolically labelled for 2 h with ^{35}S-Met, washed and lysed in 1% NP-40 (ref. 22). Postnuclear supernatants were indirectly immunoprecipitated with rabbit antibodies to mouse μ, $\gamma2$, κ and λ chains and goat antiserum to rabbit immunoglobulin[23]. After dissolving the precipitate in SDS the immunoprecipitates were reduced, electrophoresed on 11.25% SDS-Tris-glycine-polyacrylamide gels[24], and analysed by photofluorography[25]. *a, c, e, g,* Normal rabbit serum; *b, d, f, h,* rabbit anti-MPC11 ($\gamma2_b$, κ) + anti-MOPC104 (μ, λ); *a, b,* hybrid 1; *c, d,* CBOHC; *e, f,* 18–81.T5; *g, h,* hybrid 2.

0028–0836/81/090804—03$01.00

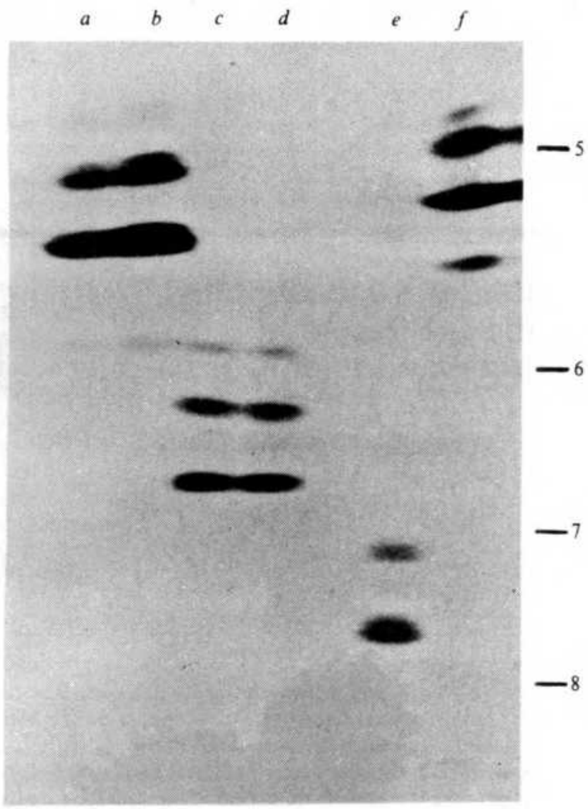

Fig. 2 Isoelectric focusing analysis of light chain from CBO cells and $NT_2 \times$ 18–81.B4 and CBOHC × 18–81.T5 hybrids. Immunoprecipitates using rabbit antisera specific for mouse κ light chain and goat antiserum to rabbit immunoglobulin were prepared from ^{35}S-Met-labelled postnuclear supernatants, reduced and electrophoresed on 9% SDS-polyacrylamide slab gels as described in Fig. 1 legend. A small strip which contained light chain was cut from the gel, equilibrated in 7M urea, 1% NP–40 and 2% ampholines, then focused on an isoelectric focusing gel (4.7% acrylamide, 0.12% *N,N*-methylene bisacrylamide, 16.6% glycerol, 7M urea, 1% NP-40, 2.5% carrier ampholines (*p*H 3.5–10), and 0.033% ammonium persulphate) according to the procedure of Burrows *et al.*[2]. The gel was analysed by photofluorography. *a*, $NT_2 \times$ 18–81. B4 hybrid 1; *b*, $NT_2 \times$ 18–81. B4 hybrid 2; *c*, CBOHC × 18–81.T5 hybrid 3; *d*, CBOHC × 18.81.T5 hybrid 4; *e*, CBOHC × 18–81.T5 hybrid 2; *f*, CBO.

light chain constant region fragment (F_{CL}) in all MPC11 myeloma cells and MPC11 variants[15,16]. Five out of six presumptive hybrids synthesize the μ and F_{CL} chains of the parent cells, but two (40%) of the immunoglobulin-expressing hybrids synthesize a full-sized κ light chain, which migrates slightly more rapidly on an SDS gel than the MPC11 κ light chain (Fig. 3). Expression of λ light chain is not detected in these hybrids[13]. Because the hybrids which express a *de novo* full-sized κ chain also express F_{CL}, and the only C_κ gene present in the NT_2 myeloma parent is expressed as F_{CL}[15,16], the synthesis of a full-sized light chain cannot be due to expression of a myeloma κ light chain gene. Therefore, the κ light chains expressed by the pre-B cell × myeloma hybrids are coded for by the pre-B cell genome.

If the 18–81 pre-B cell is already committed to expression of a particular light chain, then the same light chain should be expressed in all myeloma × pre-B cell hybrids. However, when the κ light chains from five different pre-B cell × myeloma hybrids were compared by isoelectric focusing (Fig. 2) and by peptide mapping of leucine-radiolabelled tryptic–chymotryptic peptides (data not shown), at least three different κ light chains were found. Of the five hybrids examined for the isoelectric pattern of the newly expressed light chain (Fig. 2), there were two pairs of hybrids ($NT_2 \times$ 18–81.B4, Fig. 2*a*, *b*, and CBOHC × 18–81.T5, Fig 2*c*, *d*) with indistinguishable light chains. However, the conclusion that the same light chain is expressed in independent hybrids is not justified because in each case the pair of hybrids expressing apparently identical light chains was from the same hybridization experiment.

Because somatic cell hybrids between myeloma cells and 18–81 express at least three different light chains, induction of light chain expression is probably not due to enhanced expression of a rearranged light-chain gene in the original 18–81 clone. This conclusion is supported by Southern blots, using *Bam*HI-restricted genomic fragments and a nick-translated *Bam*HI-*Xba*I fragment derived from an embryonic C_κ genomic clone as the probe[17]. The C_κ genes in 18–81, 18–81.B4 and 16 subclones of 18–81.B4 are on a 13-kilobase fragment which co-migrates with the 13-kilobase embryonic *Bam*HI fragment present in splenic DNA (data not shown). As DNA rearrangement to form active κ light-chain genes has apparently not occurred in the original 18–81 clone, there are two other possibilities: first, light-chain gene rearrangement could occur spontaneously in the 18–81 population during culture (that is, before somatic-cell hybridization). Second, rearrangement and expression of an 18–81 light-chain gene could also occur during or following hybridization of 18–81 with a myeloma cell. When 24 subclones of 18–81.B4 were analysed for light chain synthesis, none of the subclones expressed κ or λ light chain (D. Pinney and S. Riley, unpublished results). Therefore, if the light chain is rearranged spontaneously in 18–81 cells, fusion of 18–81 with a myeloma cell is required to induce detectable light chain synthesis. This

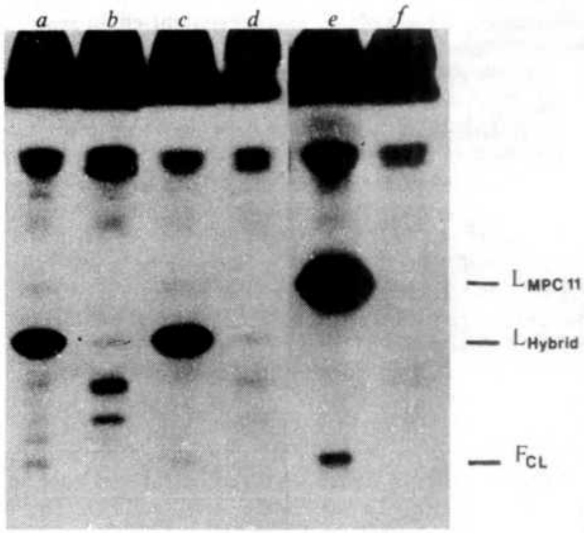

Fig. 3 SDS-polyacrylamide gel electrophoretic analysis of immunoglobulin synthesized by NT_2 myeloma × 18–81.B4 pre-B cell hybrids. The 18–81.B4 TK-negative mutant of 18–81 was selected in 30 μg ml^{-1} BUdR after mutagenesis with 125 μg ml^{-1} ethylmethanesulphonate. 4T00.A(H^-, κ^+, F_{CL}^+) is a spontaneous subline of 4T00 which no longer synthesizes detectable heavy chain. NT_2 (H^-, L^-, F_{CL}^+) is an HGPRT-negative mutant of NP_2. 4T00 (ref. 20) and NP_2 (ref. 14) were derived from the MPC11 myeloma cell line. F_{CL} is expressed in low levels in all MPC11 cell lines and its variants but is not expressed in other myeloma or 18–81 cells (data not shown). Immunoprecipitates were prepared from ^{35}S-Met-labelled postnuclear supernatants, reduced, electrophoresed on a 15% SDS-Tris-glycine-polyacrylamide gel, and analysed by photofluorography as described in Fig. 1 legend. Minor non-immunoglobulin contaminants are seen in the specific and nonspecific immunoprecipitates because the photograph was overexposed to show F_{CL}. *a*, *c*, *e*, Rabbit anti-MPC11 ($\gamma 2_b$, κ) + anti-MOPC104 (μ, λ); *b*, *d*, *f*, normal rabbit serum; *a*, *b*, $NT_2 \times$ 18–81.B4 hybrid 1; *c*, *d*, $NT_2 \times$ 18–81.B4 hybrid 2; *e*, *f*, 4T00.A.

possibility may be supported by the results of Rosenberg *et al.*[18,19] who have observed that lipopolysaccharide (LPS) can induce enhanced μ heavy chain expression and *de novo* light chain expression in some of their 18–81 sublines; although they provide no evidence to show whether LPS is inducing rearrangement of light-chain genes or is only enhancing expression of spontaneously rearranged light-chain genes. In contrast to their results, LPS has no effect on μ heavy chain expression or in inducing light chain expression in our 18–81 subline or the 24 subclones described above (D. Pinney, unpublished results).

Regardless of whether light chain rearrangement occurs spontaneously or as a consequence of cell fusion, the expression of different light chains by different hybrids suggests that when the pre-B cell light chain is expressed in 18–81 × myeloma hybrids, the 18–81 germline C_κ gene can be rearranged to at least three different κ light-chain variable region (V_κ) genes. Southern blots of DNA from pre-B cell × myeloma hybrids provide direct evidence for this rearrangement. One hybrid from each of three different κ light-chain groups, as defined by isoelectric focusing (Fig. 2), was analysed for rearrangement of κ light chains by Southern blots, using *Bam*HI-restricted genomic fragments and a nick-translated *Bam*HI–*Xba*I fragment derived from an embryonic C_κ genomic clone as the probe[17]. Each hybrid lacks the 13-kilobase C_κ fragment but contains a new rearranged C_κ which is not found in either 18–81 pre-B cells or CBOHC, CBO, NT$_2$ or 4T00.A myeloma cells. The *de novo* rearranged C_κ fragments in each of the three hybrids has a unique size compared with the *de novo* C_κ fragments in the other two hybrids (data not shown).

The development of a pre-B cell from a stem cell involves the rearrangement and expression of the μ heavy-chain gene. Rearrangement of a V_L gene to a C_L gene could occur at the same time or after rearrangement of the μ heavy-chain gene. In the former, expression of the rearranged light-chain gene would occur later than expression of the μ heavy-chain gene. In the 18–81 pre-B cell line light-chain genes are not rearranged, although our results indicate that they can be rearranged and expressed. This phenotype may be a result of transformation by Abelson virus, but it probably reflects the phenotype of a pre-B cell population in murine bone marrow, because cells expressing μ heavy chain and no light chain have been found in normal bone marrow[2]. It has been suggested that the asynchronous onset of μ and light-chain synthesis could be involved in the expression of antibody diversity[2]. That is, a pre-B cell selects a particular V_H gene and rearranges it next to the C_μ gene. The progeny of this pre-B cell may then select a V_L gene to translocate it next to a C_L gene. In this way a rapidly proliferating pre-B cell which expresses a specific heavy-chain V region is the precursor of cells which express different light chains along with this heavy chain. Our results strongly support this hypothesis.

We thank Mr James Remenick for technical assistance and N. Rosenberg and D. Baltimore for the 18–81 cell line. This work was supported by NIH research grant AI12525. S.C.R. is supported by NIH training grant 2T32-GM07082. W.M.K. is a recipient of a Research Career Development Award AI00293.

Reaction of 5-iodonaphthyl-1-nitrene with the IgE receptor on normal and tumour mast cells

David Holowka*, Carlos Gitler†, Tuvia Bercovici† & Henry Metzger*

Mast cells, basophils and a tumour analogue—rat basophilic leukaemia (RBL) cells—have a surface glycoprotein (R_ε) which specifically binds monomeric immunoglobulin E (IgE)[1], and aggregation of R_ε causes secretion[1–3]. When isolated from non-ionic detergent extracts of surface-labelled RBL cells by IgE-specific immunoprecipitation, R_ε appears as a 50,000 (50 K) to 60,000 (60 K) molecular weight (MW) band on electrophoresis in polyacrylamide gels in SDS (SDS-PAGE)[4,5]. Likewise, only a 50 K component is observed when the polypeptide that binds IgE is isolated by affinity chromatography in conditions which prevent aggregation of the IgE[6–8], even when intrinsically labelled R_ε is studied[9]. To determine how R_ε is inserted into the plasma membrane, we reacted RBL cells with the photolysable hydrophobic reagent 5-iodonaphthyl-1-azide (INA), which preferentially labels the intramembranous segments of several intrinsic membrane proteins[10,11]. We report here that, surprisingly, the label was found, not on the 50 K glycopeptide, but only on a 30 K component which other studies suggest is a subunit of R_ε (refs 9, 12).

RBL cells from the 2H3 subline were grown as described previously[13]. In some experiments cells were first incubated with IgE. Before reaction with INA, the cells were washed to remove albumin present in the serum-containing incubation medium, with which the INA can react[10,11]. Normal rat mast cells were saturated with IgE and isolated from peritoneal washings of Sprague–Dawley rats as described by Holgate *et al.*[14], omitting the final gradient step.

Radioiodinated INA was prepared on the day of the experiment from 5-amino-1-azidonaphthalene[10]. Solutions containing INA were irradiated at 25–30 °C in a water-jacketed 1-cm Pyrex cuvette with a HB0 200W 14 Osram mercury lamp at a distance of 10 cm. The light was focused with a fused quartz lens and passed through Corning CS7-60 and 054 filters to yield a band centred at ~350 nm with a halfwidth of 60 nm. In all the experiments 10^7 cells in phosphate-buffered saline, *p*H 7.4, were irradiated for 8 min in five 2-ml batches in 3 μm INA (specific activity ~1 Ci mmol^{-1}), 0.02% gelatin and 10 mM neutralized glutathione. The cells were then diluted twofold in medium containing 20% fetal calf serum and were ≥80% viable as judged by dye exclusion. The cells were washed twice and then solubilized with non-ionic detergent. IgE was added to the extracts from those cells which had not been previously reacted with it.

Figure 1 shows an experiment in which ^{125}I-INA was photolysed in the presence of RBL cells preloaded with IgE. The major band of ^{125}I counts had an apparent MW of 30 K. No discrete ^{125}I peaks occurred where a band from surface-labelled cells appears (50 K), or where the ^{131}I label on receptor-bound IgE appeared in this gel—at 80 K and 24 K. Extracts from cells incubated with IgE after reaction with INA gave indistinguishable results. Control (human IgE) precipitates contained only very low molecular weight labelled material which may represent phospholipids[11] or nonspecific small peptides.

The 50 K glycopeptide component of R_ϵ is associated specifically and stoichiometrically with a 30 K polypeptide after intact RBL cells or detergent extracts of the cells are cross-linked with dimethyl-3,3′-dithiobispropionimidate (DTBP)[12]. We tested whether the 30 K component labelled with INA might represent the same polypeptide. Cells were incubated with ^{125}I-labelled IgE amidinated to prevent its cross-linking to the receptor by DTBP at a later step[12]. The washed cells were reacted with ^{131}I-labelled INA, the detergent extract reacted with DTBP and immunoprecipitates analysed both before and after reduction with 0.25 M 2-mercaptoethanol (Fig. 2). The reduced sample showed label at an apparent MW of 30 K but none where surface-labelled receptor appears on such gels (~55 K). The unreduced sample showed only a single band for those ^{131}I counts which penetrated the stacking gel, having an apparent MW of ~90 K, exactly where cross-linked R_ϵ from surface-labelled cells appears[12]. In matched non-cross-linked samples label was observed in a 30 K but not in a 50–60 K component.

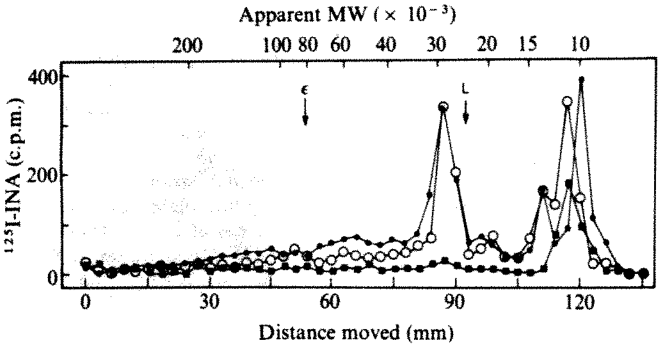

Fig. 1 SDS-PAGE patterns of immunoprecipitates from Triton X-100 extracts of cells labelled with ^{125}I-INA. Cells were lysed with 0.5% detergent in borate-buffered saline (*p*H 8.5) containing 0.5 mM phenylmethylsulphonyl fluoride and 0.5 units ml^{-1} aprotinin. After centrifugation at 50,000*g* for 30 min the extracts were diluted to 0.25% detergent and reacted with human IgE and anti-human IgE plus a *Staphylococcus aureus* Cowan preparation. The supernatant from this immunoprecipitation was then reacted with anti-rat IgE plus *S. aureus* Cowan in a similar manner. The precipitates were washed, eluted with 2% SDS and then reduced in 0.25 M 2-mercaptoethanol. ■, Extract from cells reacted with IgE before reaction with INA and precipitated with anti-human IgE and human IgE as a control. ●, Supernatant from precipitation in (■), precipitated with anti-rat IgE. ○, Extract from cells reacted with INA before addition of IgE and precipitated with anti-rat IgE (after a human IgE–anti-human IgE 'clearing' precipitation). The arrows at 80 K and 24 K are the positions at which the peaks of the ^{125}I-labelled ε and light chains of the rat IgE appeared. Electrophoresis was carried out on a 2.5–27% Isophore gradient gel (Isolab) as described elsewhere[17].

As 1 mol of R_ϵ binds 1 mol of IgE[1,8], we could compare the recovery of ^{131}I-INA-labelled components relative to the ^{125}I-IgE in the same samples. Equivalent amounts of the 30 K component were found for the reduced samples, both cross-linked and non-cross-linked. A lower amount was seen in the 90 K band of the cross-linked unreduced sample and is probably accounted for by incomplete penetration of the cross-linked receptor into the gel, which has occasionally been observed[12]. However, most of the counts which failed to penetrate the stacking gel are not due to cross-linked receptor; such material was seen variably, when it was observed it was always present in the control precipitates also, and was generally largely absent after reduction.

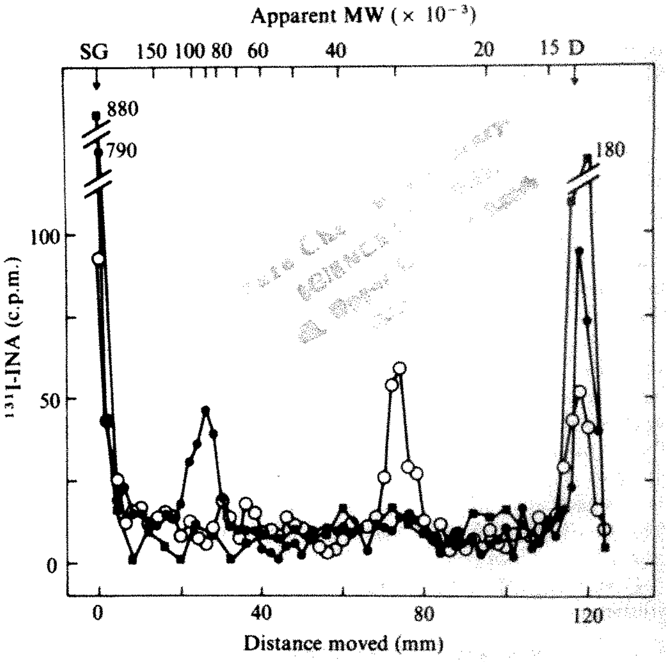

Fig. 2 SDS-PAGE patterns of immunoprecipitates from a Triton X-100 extract of RBL cells reacted with ^{131}I-INA after loading with amidinated ^{125}I-IgE. The supernatant from a 50,000*g* centrifugation was reacted with DTBP in two doses over 4 h, giving a final concentration of 10 mM. The cross-linking reagent was quenched with 100 mM ammonium acetate and the extract was then immunoprecipitated as described in Fig. 1 legend. ■, Control precipitate; ●, ○, anti-rat IgE precipitates. ○, Reduced sample; ●, ■, unreduced samples. The samples were electrophoresed on a 12% polyacrylamide gel as described elsewhere[12]. SG, stacking gel; D, bromophenol blue dye front.

Labelling of R_ϵ on normal rat mast cells gave comparable results (Fig. 3). Two peaks were observed in the specific precipitate only—a major peak at 32 K and a smaller one at 23 K. We have evidence[9] that the latter is a proteolytic fragment of the 30 K component.

R_ϵ behaves like an integral membrane protein: it requires non-ionic detergents to be solubilized and its partial specific volume suggests that it binds detergent (or lipids)[15]. Its resistance *in situ* to proteolysis[16] and its failure to be surface-labelled

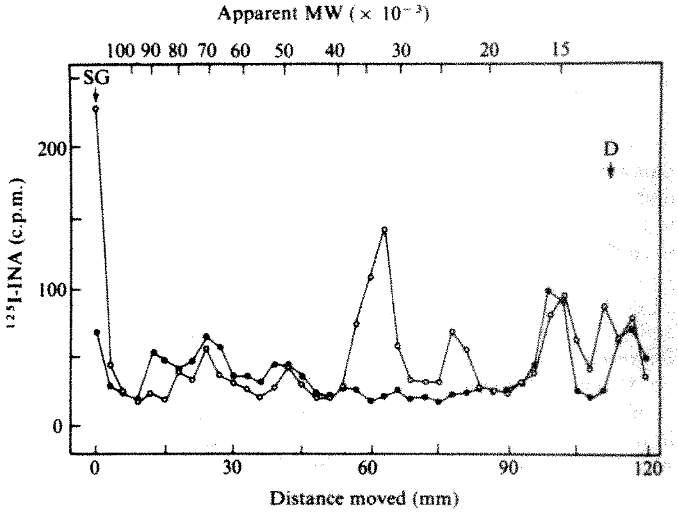

Fig. 3 SDS-PAGE patterns of INA-labelled R_ϵ from normal rat mast cells (~90% purity) preincubated with rat IgE. A Triton X-100 extract of the cells was immunoprecipitated as in Figs 1 and 2. ●, Human IgE–anti-human IgE 'clearing' precipitate; ○, specific anti-rat IgE precipitate. The SDS eluates were reduced before electrophoresis on a 12.5% polyacrylamide gel.

when IgE is bound to it[4] are also consistent with a substantial proportion of the receptor being within the plasma membrane or on its cytoplasmic side. The failure of the 50 K subunit to become labelled may result from its having only a short intramembranous segment; this segment may be interacting tightly with the 30 K subunit or membrane lipids, or its amino acid residues may be relatively unreactive. Other studies suggest preferential labelling of unsaturated over saturated lipids by INA[11] and preferential labelling of certain amino acid side chains is possible. Alternatively, the 50 K component may be anchored to the membrane solely through its interaction with the 30 K component.

Cross-linking studies had suggested that R_ε might have two subunits[12]. However, cross-linking reagents may fail to reveal associations because they depend on the apposition of suitably reactive residues. The present study shows that labelling with INA and analogous compounds may provide an alternative method for revealing presumptive subunits of membrane proteins which are undetectable by surface labelling and which may be lost during the rigorous purification often required when intrinsic labelling is used.

Expression of the *E. coli uvrA* gene is inducible

Cynthia J. Kenyon & Graham C. Walker

Biology Department, Massachusetts Institute of Technology,
Cambridge, Massachusetts 02139, USA

***UvrA*⁺-dependent excision repair[1,2] is one of the most important systems in *Escherichia coli* for repairing UV-induced pyrimidine dimers[1] and a variety of other forms of DNA damage[3,4]. The *uvrA* protein acts in conjunction with the *uvrB* and *uvrC* gene products to introduce a nick at the site of a DNA lesion and thus initiate the repair process[1]. We have recently used the Mud(Ap, *lac*)[5] operon fusion vector to identify a set of genes whose expression is induced by DNA damage. One Mud(Ap, *lac*) insertion mapped at the *uvrA* locus and made the cells sensitive to UV light. In this fusion strain, β-galactosidase expression was induced by DNA-damaging agents in a *recA*⁺*lexA*⁺-dependent fashion[6]. We were surprised by this result because *uvrA*⁺-dependent excision repair is observed both in cells in which protein synthesis has been inhibited[7] and in *recA*⁻ and *lexA*⁻ cells[8], findings which have led to the conclusion that the *uvrA* gene product is constitutively expressed and not under the control of the complex *recA*⁺*lexA*⁺ regulatory circuitry[9] (see below). We have investigated this possibility further and describe here the generation and characterization of a set of fusions of the *lac* genes to the promoter of the *uvrA* gene. We confirm that the *uvrA* gene product is induced by DNA damage in a *recA*⁺*lexA*⁺-dependent fashion.**

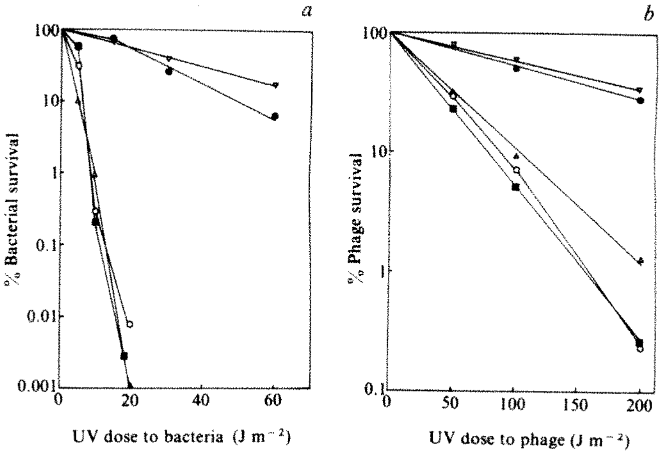

Fig. 1 *a*, Survival after UV irradiation. Fusion strains were grown in supplemented M9 minimal media[11] to a density of 1×10^8 cells ml^{-1}. Aliquots were UV-irradiated as indicated. Survival was determined by plating appropriate dilutions on supplemented M9 plates. *b*, Host cell reactivation. λcI857 was irradiated in 10 mM $MgSO_4$. 0.1 ml diluted phage was preadsorbed to 0.1 ml of an exponential culture of the indicated strain. Infective centres were scored after plating on tryptone plates and incubating at 30 °C. ▽, GW1000 (ref. 6) (parent of fusion strains); △, AB1886 (ref. 12) (*uvrA6*); ○, *uvrA215*::Mud(Ap, *lac*); ●, *uvrA215*::Mud(Ap, *lac*)/pDR2000; ■, *uvrA215*::Mud(Ap, *lac*)/pDR2026.

We were concerned that as a result of some secondary event, such as a Mu-mediated deletion[10], the Mud(Ap, *lac*) insertion at the *uvrA* locus could have become fused to the regulatory region of some gene other than *uvrA*. We therefore decided to obtain Mud(Ap, *lac*) insertions in the *uvrA* gene without imposing the requirement that the resulting fusions possess specific regulatory characteristics. Thus, we made a search for *uvrA*::Mud(Ap, *lac*) insertion mutants based on the criterion of UV sensitivity. Colonies containing random insertions of Mud(Ap, *lac*) were replica plated and UV irradiated (10 J m⁻²). Among 110,000 colonies screened, 55 UV sensitive mutants were obtained. Of these, 13 mapped at the *uvrA* locus (~50% linked to *malB* by bacteriophage P1 transduction[11]). The UV sensitivity of one of these putative *uvrA*::Mud(Ap, *lac*) isolates is shown in Fig. 1.

Like known excision repair mutants, they showed (1) a marked decrease in their ability to support the growth of UV-irradiated bacteriophage such as λ (host-cell reactivation[12]) (Fig. 1), (2) hypermutability with UV light[13] (data not shown), (3) wild-type levels of survival and mutagenesis on exposure to the methylating agent methyl methanesulphonate[14] (unpublished results).

To demonstrate conclusively that these isolates were indeed *uvrA* mutants, we carried out complementation tests. The fusion strains were transformed with the plasmids pDR2000 and pDR2026, which are derivatives of pBR322 carrying the *uvrA*⁺ gene and a *uvrA*::γδ mutation, respectively[15]. As shown in Fig. 1, pDR2000 (but not pDR2026) restored wild-type UV resistance and host-cell reactivation levels. Thus, these isolates carry Mud(Ap, *lac*)-generated insertion mutations of *uvrA*.

The original *uvrA*::Mud(Ap, *lac*) insertion mutant displayed a substantial level of β-galactosidase. The 13 new *uvrA*::Mud(Ap, *lac*) mutants fell into two classes: eight displayed levels similar to the original strain and five showed very low β-galactosidase levels. The two classes were shown to contain Mud(Ap, *lac*) insertions in opposite orientations by chromosomal mobilization experiments[11] (Table 1).

The two classes of *uvrA*::Mud(Ap, *lac*) mutants were tested for mitomycin C inducibility of β-galactosidase. As expected, β-galactosidase levels in strains in which *lac* was integrated opposite to the direction of transcription were unaffected by mitomycin C. However, the eight isolates containing *lac* oriented in the direction of transcription each showed a stimulation of activity on exposure to the chemical (Fig. 2*a*). These same strains showed a similar inductive response to UV irradiation and treatment with nalidixic acid. Thus, transcription of the *uvrA* gene seems to be stimulated by agents that either damage DNA or block DNA replication.

The induction of *uvrA* is only one of several bacterial responses to DNA damage. Treatment of cells with a variety of DNA-damaging agents (including those mentioned above) triggers expression of the 'SOS' functions. These include the induction of certain prophages such as λ, the induction of the *recA* protein, and filamentous growth[16]; at least some of these 'SOS' responses may be due to increased expression of the set of *din* genes[6]. All these phenomena are coordinately regulated by the *recA* and *lexA* proteins. The *lexA* protein has been identified as the repressor of the *recA* gene[17] (D. W. Mount and J. W. Little; R. Brent and M. Ptashne, personal communication); the *lexA* gene product has a negative regulatory effect on the *lexA* gene itself[18] as well as on *din* genes (C.J.K. and G.C.W., unpublished). The regulatory effects of *recA* seem to be due to the proteolytic activity of the *recA* protein which can cleave both the *lexA* protein[19] and λ repressor[20].

We have examined the mechanism by which *recA* and *lexA* act to regulate the *uvrA* gene product. Induction is controlled by the 'SOS'-regulatory circuitry, as the introduction of *recA*$^-$ and *lexA*$^-$ (uninducible repressor) mutations prevents increased β-galactosidase expression in the fusion strains (Fig. 2*a*). Furthermore, an allele of *recA* (known as *lexB30*, ref. 21), which specifies a *recA* protein deficient in proteolytic activity but not recombination functions (J. Roberts, personal communication), also reduces the induction (data not shown). This suggests that the *recA* protein is functioning as a protease in the induction process.

If, like *recA* and *lexA*, *uvrA* is directly repressed by the *lexA* protein, then *uvrA*::Mud(Ap, *lac*) fusion strains lacking the *lexA* gene product should produce high levels of β-galactosidase regardless of whether the *recA* protein is proteolytically active. As shown in Fig. 2*b*, cells carrying a putative null allele of *lexA* called *spr* (ref. 17) synthesize high levels of β-galactosidase in a *recA*$^-$ background. Thus, the *lexA* protein may also repress the *uvrA* gene, with induction occurring when the *recA* protein proteolytically inactivates the *lexA* protein in response to DNA damage.

Table 1 Orientation of Mud(Ap, *lac*) in representative *uvrA*::Mud(Ap, *lac*) insertion mutants

	Pur$^+$ recombination per 10^6 donor cells	
	Donor	
Recipient	*uvrA215*:: Mud(Ap, *lac*)/ $F_{ts1141lac}$	*uvrA223*:: Mud(Ap, *lac*)/ $F_{ts1141lac}$
purD::Mud(Ap, *lac*)	510	48
purA::Mud(Ap, *lac*)	2	1,780

$F_{ts114lac}$ (ref. 27) was introduced into GW1000 derivatives carrying *uvrA215*::Mud(Ap, *lac*) (Lac$^+$, inducible) and *uvrA233*:: Mud(Ap, *lac*) (Lac$^-$, uninducible). Representative members of the two classes would be expected to transfer host genes in opposite directions when an F' *lac* was integrated into the *lac* gene of Mud(Ap, *lac*) to form an Hfr. Cultures of these strains contain a small fraction of Hfrs resulting from F' integration into Mud(Ap, *lac*) via *lac* homology. The resulting gradient of transfer of chromosomal markers depends on the orientation of Mud(Ap, *lac*) within *uvrA*. Recipients were derivatives of BW545 (*lacΔU169 rpsL1*) bearing *purA*::Mud(Ap, *lac*) and *purD*::Mud(Ap, *lac*) insertions (E. Trefelner and G.C.W. unpublished). (The *purA* and *purD* genes map on either side of *uvrA*.) The presence of Mud(Ap, *lac*) in the recipient prevented killing due to zygotic induction of Mu functions. Equal volumes of exponential cultures were mixed and incubated at 34 °C for 30 min. Matings were interrupted by vortexing and 0.1-ml aliquots were plated on minimal plates lacking adenine and donor nutrients. Plate matings were prevented by shifting the cells to 43 °C after 3 h at 34 °C; only Pur$^+$ recombinants escape killing by Mud(Ap, *lac*) *cts* induction. Given the known orientation of *lac* on $F_{ts114lac}$, we conclude that *uvrA* is transcribed in an anticlockwise direction on the *E. coli* chromosome.

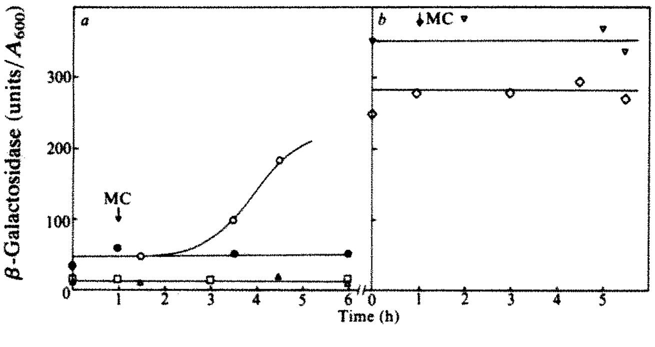

Fig. 2 Kinetics of induction of β-galactosidase in *uvrA*::Mud(Ap, *lac*) fusion strains. Exponential cultures growing in supplemented M9 media were treated with MC (1 μg ml^{-1}) as shown and the specific activity of β-galactosidase determined as described elsewhere[6]. *a*, ●, *uvrA215*::Mud(Ap, *lac*), no MC; ○, *uvrA215*::Mud(Ap, *lac*); □, *recA uvrA215*::Mud(Ap, *lac*); △, *lexA uvrA215*::*Mud*(*Ap, lac*); *b*, ▽, *spr uvrA215*::Mud(Ap, *lac*); ◇, *spr recA uvrA215*::Mud(Ap, *lac*). The effect of the *uvrA* gene product on induction was determined by introducing pDR2000 into wild-type, *lexA*$^-$ and *recA*$^-$ cells. No significant differences in induction profiles were observed (data not shown).

Our suggestions concerning the inducibility of *uvrA* have been recently directly confirmed by Kacinski, Rupp and Seeberg (personal communication), who have found that *uvrA* protein is constitutively expressed at high levels in a *spr recA* strain, and that synthesis of *uvrA* protein is induced by nalidixic acid, a treatment which induces SOS functions.

During our search for UV-sensitive mutants, we isolated two putative *uvrB*::Mud(Ap, *lac*) fusions. These (1) map at the *uvrB* locus (20% co-transducible with *gal* by bacteriophage P1 transduction), (2) give rise to the same set of excision repair-deficient phenotypes as do the *uvrA* insertions, and (3) synthesize β-galactosidase. Although, curiously, these fusions show little mitomycin C inducibility, they display levels of UV and nalidixic acid inducibility comparable with the *uvrA* fusion strains (data not shown).

The findings that components of the excision repair system are synthesized at increased levels in response to DNA damage imply that *E. coli* induces certain repair capabilities as part of its overall defence strategy. The inducibility of excision repair components helps explain certain earlier observations. First, inactivation of the *lexA* protein (which results in the induction of the *uvrA* gene product) increases the UV resistance of *recA* mutants; this increased resistance is dependent on a *uvrA*$^+$ genotype[22]. Second, *recF* and *umuC* mutants show decreased levels of inducible (Weigle[16]) reactivation of UV-irradiated bacteriophage; in each case a *uvrA* mutation eliminates the remaining activity[23,24].

The specific mechanism by which induction of the *uvrA* gene product enhances cell survival is unclear. In conditions in which *uvrA*$^+$-dependent inducible UV resistance is observed, there seems to be no increase in the levels of 'short patch' excision repair[25]. Thus, these proteins may be functioning in another repair process. One such possibility is another type of excision repair called 'long patch' repair[26]. Like the induction of the *uvrA* gene product, long patch repair is *recA*$^+$*lexA*$^+$ dependent.

We thank A. Bagg, S. Elledge, P. Langer, J. Mulligan, P. Pang, K. Perry, W. Shanabruch, E. Trefelner and S. Winans for valuable discussions, L. Withers for help in preparing the manuscript, and especially B. M. Kacinski, W. D. Rupp, E. Seeberg, P. K. Cooper, J. Roberts, D. M. Mount and J. W. Little for sharing information before publication. Binding of an SV40 T antigen-related protein to the DNA of SV40 regulatory mutants

R. McKay

When simian virus 40 (SV40) infects host cells, the viral genes are expressed in two phases. Early in infection, the virus genome is transcribed and translated to yield two related proteins, 'large T' and 'small t' antigens. Later the rate of synthesis of the early messenger RNA falls and the viral genes coding for the coat proteins are transcribed and translated. Early gene transcription is inhibited only when an active large T antigen is present in the cell (for review see ref. 1). These and other observations have led to the hypothesis that T antigen acts as a negative feedback repressor of its own RNA transcript[2–4]. The properties of SV40 tsA mutants, which produce temperature-sensitive T antigen, provide evidence for another role of T antigen—in the initiation of viral DNA replication[5]. Mutations around the origin of DNA replication in SV40 lead to a *cis*-acting defect in DNA replication[6,7]. These mutations fall outside the region of the A gene which codes for T antigen but within the region known to bind T antigen[8] and the closely related and more easily prepared D2T protein[9,10] which is synthesized by an adeno–SV40 hybrid virus Ad2D2 and seems to differ from SV40 T antigen only in its amino-terminal segment[11]. Revertants of origin-defective mutants have been isolated with second site mutations within the DNA A gene coding sequence[12]. These data support the view that T antigen modulates transcription and replication of SV40 DNA by binding to one or more sites in and around the viral origin of replication. We present here evidence to show that mutants of SV40 carrying constructed mutations in the regulatory region[13] show reduced binding of D2T protein *in vitro*. This is the first demonstration in a eukaryote that a mutation in a regulatory DNA sequence alters the binding of a controlling protein *in vitro*.

Figure 1 shows the organization of the relevant part of the regulatory region in SV40. There are apparently three tandem D2T protein binding sites[9,10] spanning a segment known to be involved in the control of DNA replication[6,7,13,14]. The 5′ termini of the early mRNA and some of the late mRNAs also fall in this region of the DNA[15,16]. The sequence of this segment of wild-type DNA and of the three mutant DNAs used in this study are shown in Fig. 1. The mutants cs (cold-sensitive for plaque formation) 1088 and 1085 were constructed by site-specific mutagenesis[13]; their altered sequences fall within the region defined by DNase and methylation protection studies as the first D2T protein binding site[9,10]. By contrast, the mutant 812 lacks the second and third binding sites but the first site is unaltered[7]. These changes in sequence around the origin of replication allow distinction of the contribution of different parts of the regulatory region to T antigen binding.

An immunoassay for DNA-protein interaction has recently been developed[17]. An important feature of immunoassay procedures to study hormone–receptor interactions is that quantitative measurements of affinity can be made in the presence of complex protein mixtures. The ability to manipulate DNA suggests that DNA fragments of defined sequence can be used, like hormones, as probes for high-affinity DNA binding proteins in complex cell extracts. Assays of this sort are simple to perform, can be used to screen many samples such as mutant viruses and may be particularly valuable in studying the specific binding of regulatory proteins to chromatin rather than DNA. The defective adenovirus Ad2D2 synthesizes a protein related to SV40 T antigen[11]. This protein, D2T, is known to bind preferentially to DNA sequences around the SV40 origin of replication[10]. Using a monoclonal antibody (RMT-1) specific for SV40 T antigen, DNA fragments containing the regulatory sequences around the wild-type replication origin are preferentially precipitated. The controls in this experiment are of two types: first, extracts of HeLa cells infected with adenovirus Ad2$^+$ alone show no preferential precipitation of DNA fragments containing the SV40 origin. Second, SV40 DNA fragments lacking the origin of replication are only immunoprecipitated by partially purified D2T when the protein is present in excess and all the origin-containing fragments are already bound by D2T. The immunoassay was used to obtain both kinetic and equilibrium measurements of the affinity of DNA–protein interaction. Both the half life of the complex once formed and a Scatchard equilibrium treatment gave data consistent with an equilibrium dissociation constant of 10^{-12} M. Similar values have been obtained with the nitrocellulose filter binding assay[18].

Site-specific mutagenesis in the regulatory region of SV40 gives viruses with altered properties. The explanation proposed for this alteration in phenotype is that the interaction of T antigen with DNA is changed in the mutant virus. Consistent

Fig. 1 The structure of the regulatory region of SV40. The wild-type DNA sequence around the origin of SV40 replication is shown in the middle of the figure (numbered according to the BB convention[1]). Arrows indicate cleavage sites for the restriction endonucleases *Hin*dIII and *Bgl*I. The initiation codon for large T and small t antigens and the ATTTAT box are enclosed on the early sense strand. Above this are shown the sequences protected by D2T from methylation and DNase I digestion[9,10], the 5′ end and direction of transcription of early mRNA[16] and the limits of the replication origin[13,14]. Below the wild-type sequence the structure of mutant DNAs used in this study are shown[7,13]. The base substitutions generated in cs 1088 by bisulphite treatment are shown in larger type. Note the two new *Hin*dIII sites in this mutant. b.p., Base pairs.

with this view, second-site revertants to wild-type phenotype have been mapped to the structural sequences coding for SV40 large T antigen[12]. Using a series of deletions around the origin the sequences responsible for the preferential immunoprecipitation of the regulatory region have been mapped within the limits of base pair 5 to base pair 5,189 (ref. 17). Here we have studied the specific D2T binding to virus genomes carrying less drastic alterations in their regulatory region. Our results show directly that these mutant viruses are altered in their ability to interact with a regulatory DNA binding protein.

When SV40 DNA is cut with the enzyme *Bst*NI (an isoschizomer of *Eco*RII, ref. 19), the origin of replication and the D2T protein binding sites are contained in the 311-base pair G fragment. After incubation of ^{32}P-labelled, *Bst*NI-digested wild-type SV40 DNA with D2T protein followed by immunoprecipitation with anti-D2T antibody, this fragment is preferentially recovered (Fig. 2). By contrast, *Bst*NI G fragments derived from cs 1088 and cs 1985 DNA and carrying mutations in the first binding site show a greatly reduced level of specific binding (Fig. 2). As the *Bst*NI G fragment of cs 1085 (containing a deletion of 21 base pairs) can be resolved from the wild-type G fragment by gel electrophoresis, mixtures of wild-type and mutant fragments could be tested for relative binding of D2T protein. The result confirms that D2T protein binds the mutant fragment markedly less than the wild-type fragment. As noted in Fig. 2 legend, the binding assays were carried out at a concentration of 20mM NaCl. At high concentrations of NaCl specific binding was inhibited, presumably due to inhibition of ionic interactions between D2T protein and the binding site, but the differential binding of mutant and wild-type G fragment was apparent at all salt concentrations tested.

The binding of the origin-containing DNA restriction fragment was measured relative to another restriction fragment. The autoradiograph shown in Fig. 2 was analysed using a computerized scanning system with four elements: (1) Optronix P1000 scanner; (2) PDP 11/60 computer; (3) Grinnel graphics system, and (4) the QUEST software system (J. Garrels, Cold Spring Harbor Laboratory). The ratio of the integrated intensity of the *Eco*RII/G fragments was 6.5 (s.d. ± 1.3) for wild-type DNA, 1.87 (s.d. ± 0.44) for the mutant cs 1085 and 0.81 (s.d. ± 0.25) for the mutant cs 1088. Note that the *Eco*RII/C fragment is 673 base pairs long and the Eco RII/G fragment only 311 base pairs, thus the relative molar binding of wild-type RII/G to RII/C fragments is 13.3. These figures clearly show that

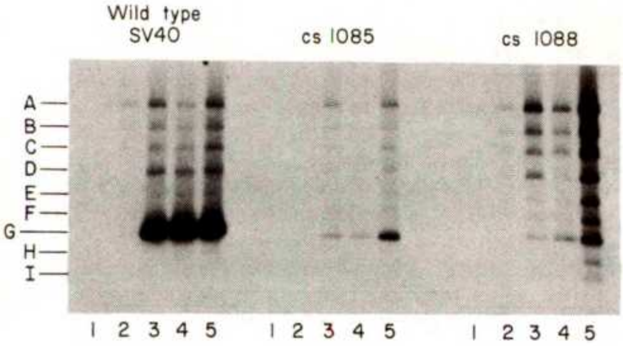

Fig. 2 Immunoprecipitation of SV40 DNA restriction fragments bound by D2T protein. 5 ng of *Bst*NI-digested SV40 or mutant DNA (specific activity 5×10^7 c.p.m. μg^{-1}) were incubated with increasing amounts of partially purified D2T protein: 1, 0 μl; 2, 25 μl; 3, 100 μl; 4, 200 μl; 5, 300 μl, in 20 mM sodium chloride, 2.0 mM dithiothreitol (DTT), 0.1% bovine serum albumin, 0.1 mm EDTA, 0.05% NP40, 40 $\mu g\ ml^{-1}$ phenylmethylsulphonyfluoride, 3% dimethyl sulphoxide, for 10 min at 25 °C. All the experiments reported in this paper were carried out with the same partially pure preparation of the D2T protein. The bound DNA fragments were then immunoprecipitated by addition of 30 μl of monoclonal anti-D2T antibody for 10 min, followed by 20 μl of rabbit anti-mouse immunoglobulin and 60 μl of fixed *Staphyloccocus aureus*. The detailed characterization of this assay is described elsewhere[17]. The immunoprecipitated fragments were released from the fixed bacteria with 1% SDS in 10 mM Tris-HCl *p*H 8.0/1 mM EDTA and analysed by agarose gel electrophoresis and autoradiography. Fragment G contains the replication origin and adjacent sequences. The D2T protein used in this assay was partially purified from HeLa cells infected with $Ad2^+D2$ virus (50 plaque-forming units per cell) and grown at 37 °C for 30 h. Nuclei were prepared by hypotonic lysis and the nuclear D2T protein extracted in buffer A (0.15 M NaCl, 10 mm Tris-HCl *p*H 8.0, 1 mm EDTA, 0.5 mm DTT). This crude nuclear fraction was further purified by chromatography on DE52 (elution in 0.25 m NaCl, 10 mm Tris-HCl *p*H 8.0, 1 mm EDTA, 0.5 mm DTT). This fraction was then precipitated with 50% ammonium sulphate, dissolved in buffer A plus 30% glycerol and stored at −70 °C. Polyacrylamide gel electrophoresis showed D2T to be one of four major proteins present at this stage.

quantitative scanning of the autoradiograph in Fig. 2 confirms that mutations in the first D2T binding site substantially reduce the D2T-mediated precipitation of these DNA fragments.

In Figure 3 the binding of the *Hin*dIII fragments of wild-type SV40, cs 1088 and 812 are compared. The base substitution in cs 1088 generate two new *Hin*dIII restriction sites close to the start of the second D2T protein binding segment[13]. These new restriction sites allow the preparation of a DNA fragment containing only binding segments 2 and 3; as seen in Fig. 3 this fragment shows only very slight preferential binding to D2T protein. In contrast, the wild-type and 812 *Hin*dIII fragments bind D2T protein strongly. Note that in the case of mutant 812 this strong binding occurs in the absence of the second and third sites. We can conclude that the first site alone can bind D2T protein tightly, but the second and third binding sites are not strong independent sites.

Our main conclusion from these studies is that mutations in a regulatory segment of the SV40 genome, outside structural gene sequences, affect the interaction of this segment of viral DNA with a regulatory protein. Mutations located in the previously defined first D2T protein binding site within the regulatory segment[9,10] cause a marked decrease in binding of the D2T protein. (Recently we have found that these mutations also cause diminished binding of T antigen partially purified from SV40-infected monkey cells.) The decreased binding is not related to the use of monoclonal antibody in our assay, as serum from hamsters bearing SV40-induced tumours served equally well. In contrast, mutations in the second T antigen binding site had little or no effect on binding of D2T protein (Fig. 3 and ref. 17). Thus it seems that D2T protein can bind independently to the first site, but poorly or not at all to the isolated second plus third sites. Testing of other mutants with base pair substitutions in this region should help determine which bases contribute most to the specific interaction with D2T protein and with T antigen.

The cold-sensitive regulatory mutants used in this study form small plaques at 32 °C but wild-type plaques at 37 and 40 °C (ref. 13). They therefore seem to have a defect in virus growth at the lower temperature, previously postulated to be due to cold-sensitive interaction of a regulatory protein with an altered signal in the viral DNA[13]. We attempted to demonstrate a differential effect of temperature on the binding of D2T protein to mutant DNA fragments, but due to greater non-specific binding at elevated temperatures, a clear effect was not found.

Regarding the possible physiological significance of the interaction of T antigen in the first binding site of the SV40 regulatory segment, an attractive hypothesis is that this interaction is responsible for inhibiting transcription of the gene for T

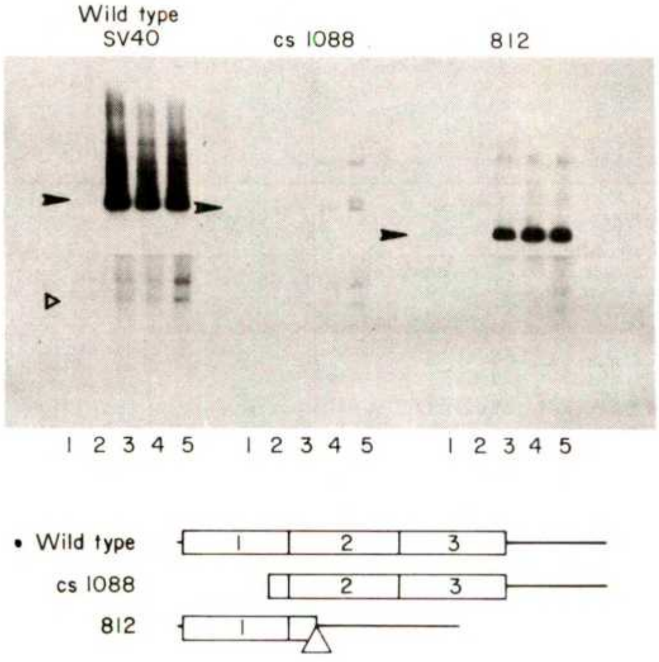

Fig. 3 Immunoprecipitation of *Hin*dIII DNA fragments containing different combinations of the three D2T protein binding sites. The structure of the *Hin*dIII fragments spanning the origin is shown in the lower half of the figure with D2T binding sites represented by numbered boxes. The wild-type *Hin*dIII fragment starts close to the first site and spans all three sites. The *Hin*dIII fragment from deletion mutant 812 contains only an intact first site. The *Hin*dIII fragment derived from cs 1088 contains only sites 2 and 3. The D2T binding properties of these fragments were assayed as described in Fig. 2, using 100 μl of D2T per point. The solid arrowheads indicate the position of the origin-containing fragments after immunoprecipitation and electrophoresis; the open arrowhead shows a smaller *Hin*dIII restriction fragment of SV40 used as an internal control in computerized scanning of the autoradiograph. The lower half of the figure has been overexposed to show the control fragments. Integrated intensity in the origin fragment relative to the control fragment was 10.75 for wild-type DNA, 4.39 for the mutant cs 1085 and 8.79 for the deletion mutant 812 which lacks the second and third binding sites. The high binding of fragments larger than the origin-containing fragment of wild-type SV40 DNA is caused by a small proportion of partial restriction fragments. These immunoprecipitated partial fragments were not included in the relative binding figures given.

antigen. Consistent with this possibility are the presently known properties of mutants cs 1085 and cs 1088, that is, overproduction of early viral RNA and T antigen, and nearly normal rates of viral DNA replication (D. D. and D. Nathans, unpublished observations). More detailed studies of these and similar mutants, including *in vitro* transcription of their DNAs, will be required to test this hypothesis fully.

We thank Yakov Gluzman for DNA from mutant 812, Joe Sambrook and Daniel Nathans for support and critical reading of this manuscript. This research was supported by grants from the US NCI (2 P01 CA 16519 and CA 13106-09). D.D. is a trainee under the Medical Scientists Training Program of the US National Institutes of General Medical Sciences (grant no. GM 07309). During part of this work R.M. was a Research Fellow of the MRC.

Network structure in gels of rod-like polypeptides

Kohji Tohyama & Wilmer G. Miller

Department of Chemistry, University of Minnesota, Minneapolis, Minnesota 55455, USA

The formation of a mechanically self-supporting, macromolecular gel or network is understood on a molecular scale in terms of cross-links or branch points, either of a permanent nature by covalent bond formation, or of a reversible nature, such as in the gelation of gelatin. In thermally reversible gels each branch point may contain numerous monomeric units, indicative of local crystallite or aggregate formation, as in cellulose acetate[1] or gelatin[2–4], or only two monomeric units as in polyacrylylglycinamide[5]. The formation of reversible networks in nonionic, rod-like polypeptide homopolymers[6–8], particularly at low concentrations (<0.1 wt%), is surprising in that the molecular origin of the branch points is not obvious. We have suggested previously[8] that this network constitutes a thermodynamic phase resulting from a particular kinetic mechanism of phase formation made favourable by the unusual polymer–diluent phase equilibria occurring with stiff-chain polymers. Here, the network is visualized by electron microscopy, and shown to be compatible with the proposed mechanism.

Examples of gels visualized by microscopy are shown in Fig. 1. Typically, an isotropic solution was cooled to the desired gelation temperature, held overnight, quenched in Freon 22 cooled with liquid nitrogen, and at −150 °C fractured, etched, shadowed (Pt–C) and replicated with a thick carbon layer. The replica, after removal of polymeric material, was viewed in a Zeiss 9 S-2 electron microscope. Polybenzylglutamate (MW 200,000) networks generally appeared random (Fig. 1*a*); occasionally regions seemed to have been under uniaxial deformation when quenched (Fig. 1*b*). Virtually all strands begin and end at branch points.

A freshly fractured surface was shadowed without etching. A typical micrograph (Fig. 1*c*) shows many ends and spurs, as one might expect with a fractured network. Occasionally a fracture-knife gouge across a network strand was clearly visible. Furthermore, micrographs from isotropic solutions cooled rapidly through the gelation region by quenching in liquid nitrogen showed no network structure. These results indicate that the visualization of the polypeptide networks was not an artefact of sample preparation.

For comparison a network formed from a more flexible polymer was visualized—a gelatin network (Fig. 1*d*). The micrograph is quite distinct from the polypeptide micrographs, but similar to micrographs of agar and acrylamide gels prepared in a similar manner[9,10]. Micrographs of other gels have been obtained using different preparation techniques[2,11,12]. However, we show elsewhere[13] that our gelatin micrograph is an artefact of sample preparation.

The micrographs of the polypeptide networks reveal strands or fibres with cross-links that do not result from the contact of nonaligned fibres, that is, the cross-links/branch points tend not to have four arms. The fibres are of diameters ranging from hundreds to more than a thousand angstroms, and are composed of bundles of aligned rods (rod diameter ~20Å). The spacing between fibres seems to be typically of the order of 1 μm. These values are not certain as the platinum may shadow polymer and solvent differently in the unetched samples, and a depth scale is lacking in the etched samples. However, etched and unetched samples do give similar results.

We believe that the origin and structure of these networks may be the result of the kinetics of phase separation. Typically, when a solution is brought from a uniphasic into a biphasic region the new phase forms by a nucleation and growth mechanism. However, if the solution is brought into a region of thermodynamic instability ($\sigma^2G/\sigma c^2 < 0$ where G = Gibbs free energy and c = concentration) rather than metastability, the spinodal decomposition theory of Cahn and Hilliard[14] predicts phase separation by a non-nucleation mechanism, whereby the spatial variation in solution composition is continuous with a characteristic periodicity. Material flows spontaneously against a concentration gradient. Early in the phase separation each phase is predicted to be continuous in the other phase. In systems which flow, ageing occurs by tube flow[15], leading eventually to the breakup of the network-like morphology. Most aspects of the theory have been tested experimentally[15–21].

Application to the polypeptide gels is made by reference to the Flory phase diagram for rigid rod polymers (Fig. 2) which corresponds closely to that observed for polybenzylglutamate[7,22]. A network forms when a solution is cooled and crosses into the wide biphasic region (designated 'Network'). The very drastic polymer–solvent unmixing which occurs with only a slight change in polymer–solvent interaction should allow entry into the unstable region even at low concentrations. Thus, if phase separation occurs by spinodal decomposition, the network which forms is simply the polymer-rich phase, a damp fibre, which is bicontinuous with the solvent-rich phase. The polymer-rich phase has no tendency to flow, which accounts for the persistence of the network after phase separation is complete. The mean periodicity in concentration fluctuation can be predicted[18,19,23], which should correspond to the interfibre spacing. Fibre thickness may then be calculated by mass balance. Application to our samples predicts a spacing of the order of 1 μm and a mean fibre thickness of several hundred angstroms[23], which agree with our observed values.

Other rod-like synthetic polymers form gels[20]. Also, many biological macromolecules form rod-like assemblies and gels, which sometimes affect cell morphology, for example, sickle-cell

0028–0836/81/090813—02$01.00

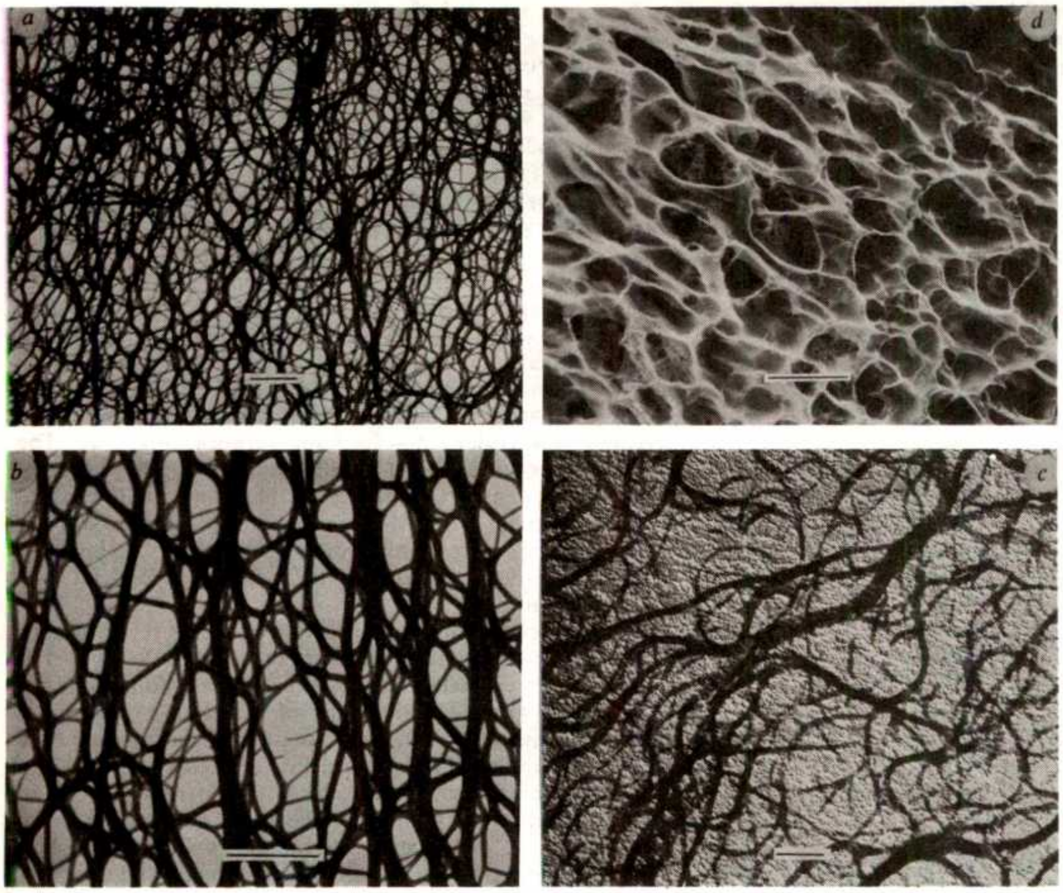

Fig. 1 Electron micrographs of 1 wt% polybenzylglutamate gels (*a–c*) and of a 3 wt% gelatin gel (*d*). Scale bar 1 μm. Etch times: 10 s (*a*, *b*), 0 s (*c*), 60 s (*d*).

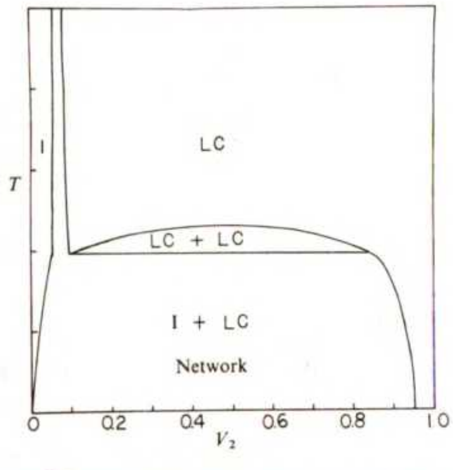

Fig. 2 Flory[22] temperature–composition (volume fraction polymer) phase diagram for rigid rod–diluent (rod axial ratio 150), which corresponds closely to that observed for polybenzylglutamate[7]. A network (gel) forms when a solution is cooled and crosses into the wide biphasic region (Network). The phases present are isotropic (I) and liquid crystalline (ordered) (LC).

haemoglobin, actin, tubulin and tobacco mosaic virus[20,24–26]. Thus the mechanism by which a rod-like polymer forms a network spanning the confining vessel may be of interest in understanding passive structure formation in more complex systems.

Structure of the protein and DNA in fd filamentous bacterial virus

D. W. Banner, C. Nave & D. A. Marvin

European Molecular Biology Laboratory, Postfach 10.2209,
6900 Heidelberg, FRG

The virion of filamentous bacterial viruses comprises a cylindrical protein shell of o.d. ~60 Å and i.d. 20 Å, containing a single-stranded circular DNA molecule which has two oppositely directed but not base-paired strands extending the length of the virion. The assembly of the virion involves an intracellular prepackaging of the DNA with a viral DNA-binding protein which is then displaced by the coat protein as the

0028-0836/81/090814—03$01.00

growing virion crosses the bacterial membrane[1]. Studies of the virion by X-ray fibre diffraction show that the protein coat consists largely of α-helices oriented roughly parallel to the axis of the virion[2,3]. As the normal to a planar peptide tends to align normal to a magnetic field, it is possible to improve significantly the orientation of virions in fibres using a strong magnet[4,5]. The success of this technique with the Pf1 strain of virus led us to apply it to the better-known fd (f1, M13) strain. We report here new information about the arrangement of protein and DNA in the fd virion obtained from the improved diffraction pattern (Fig. 1).

The fd virion is ~8,700 Å long; its DNA contains 6,408 nucleotides, and its coat contains ~2,760 50-residue protein molecules. The distribution of intensity on the fd fibre patterns indicates that rods of electron density slope from large to small radius and also slew radially, as proposed[6] for the similar virus Pf1. The position of layer lines on the diffraction patterns gives information about the relative positions of the protein subunits. There is a set of layer lines at orders of 32 Å, and a set of meridional reflections at orders of 16 Å. Calculation of mass per length (as described in Table 9 of ref. 7) using accurate molecular weight data derived from the DNA sequence[8], shows that in the 16-Å repeat distance there are 5.1 protein subunits (±7%) and 11.8 nucleotides (±4%). These numbers imply 2.72 Å average axial separation between nucleotides in each of the two DNA strands.

The meridional reflection at 16 Å was previously interpreted[3] as being due to a periodic perturbation of a helical arrangement of subunits, with a repeat of the perturbation every five subunits. This perturbation predicts satellite layer lines which could not be seen on poorly oriented patterns, but their possible presence could not be ruled out. These satellite layer lines are clearly absent on Fig. 1, therefore such a perturbation is not supported by the data. An alternative interpretation[9,10] of the 16-Å meridional reflection is that the virion symmetry involves a 5-fold axial rotation axis combined with a 2-fold axial screw axis of pitch 32 Å (Fig. 2). The difference between this kind of arrangement and a perturbed helix is small (see ref. 11, Fig. 10). In particular, subunits with the same shape as in the perturbed helix model pack well (Fig. 3) in the symmetry of Fig. 2, and give a calculated diffraction pattern which agrees with the strong 10-Å equatorial and near-equatorial observed data (Fig. 4). The local interactions between nearest neighbours shown in Fig. 3 are similar to those of the structurally related virus Pf1 (ref. 10; Fig. 3) at 7 Å resolution.

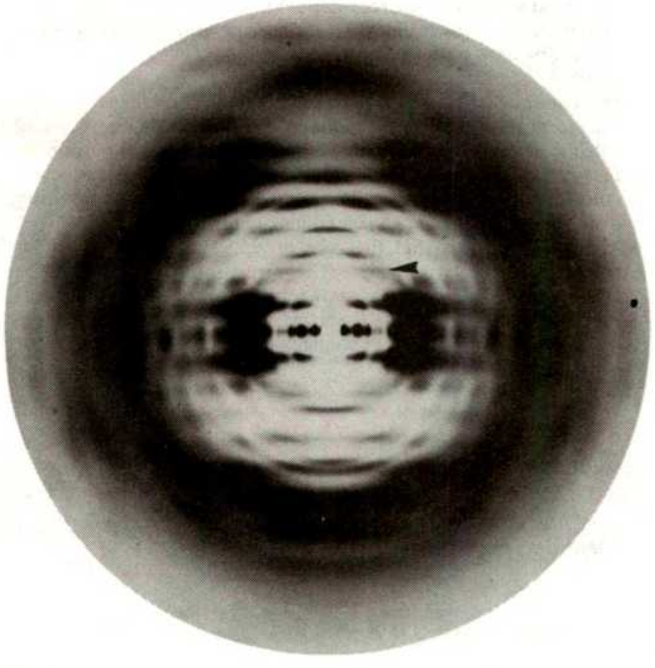

Fig. 1 X-ray fibre diffraction pattern of fd filamentous virus. Fibre axis vertical. Preparation of virus and X-ray fibre diffraction techniques are described elsewhere[3]. In the purified virus solution, >98% of the protein migrated with the major coat protein and >95% of the DNA migrated with viral DNA in appropriate gel electrophoreses. The virus solution was titrated to *p*H 2 (below the isoelectric point) before preparing fibres, because fibres prepared from virus solutions at neutral *p*H give double orientation (A. Fowler, personal communication). Protein layer lines occur at orders of $c = 32.3$ Å with meridional reflections on even layer lines. DNA layer lines occur at 26.7, 13.35 (arrow), 3.42 and 3.02 Å. Unit cell parameter $a = 60.7$ Å; 92% relative humidity; specimen–film distance 4.20 cm; tilt 16.6°; standard deviation of disorientation 3.5°. Fibre fd 45.2; film 5148. ×1.6.

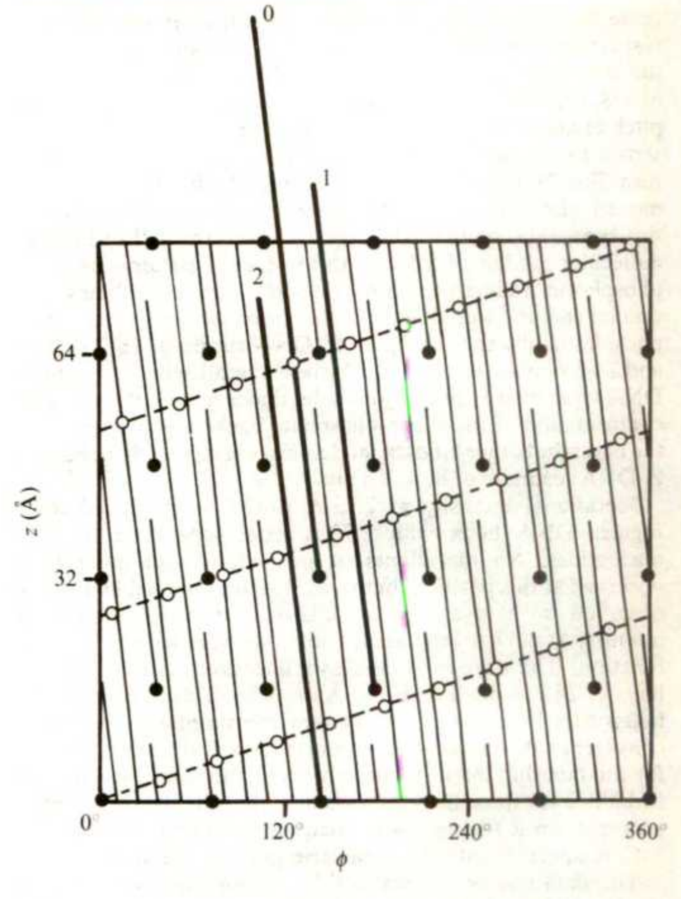

Fig. 2 Surface lattice of the fd virion. The surface lattice is generated by projecting equivalent points along radii onto a cylinder of 13 Å radius, and then cutting the cylinder along a vertical line to give a 2-dimensional representation. ●, Projections of equivalent points in each protein subunit, and the solid lines represent the projections of the α-helix axes. The bold solid lines indicate the three nearest neighbours shown in Fig. 3. ○, Projections of equivalent points in each DNA nucleotide pair, and the broken line represents the projection of one strand of the DNA helix. The fact that the DNA helix passes through surface lattice points of the protein at a (ϕ, z) of (0, 0), (72°, 32 Å), and (144°, 64 Å) may be fortuitious, but note that a nucleotide/protein ratio of 2.30 would give identical DNA–protein environments every 23 nucleotides along one DNA strand (every 64 Å along the axis), and a nucleotide/protein ratio of 2.40 would give identical DNA–protein environments every 12 nucleotides (every 32 Å). The relative phase of the DNA and protein is unknown; that is, the DNA helix could be shifted in ϕ and/or z relative to the protein helix. The line-group symmetry[14] of the protein assembly is **sr**, $N = 5$.

The diffraction patterns of magnetically aligned fd often show faint layer lines at the first two orders of a 26.7-Å periodicity. If these layer lines are attributed to J_1 and J_2 Bessel functions respectively, the radial positions of the intensity maxima along the layer lines would correspond to electron density at a radius of ~8.5 Å. We interpret these layer lines as being due to the pitch of helical viral DNA. DNA of this pitch with 2.72 Å axial separation between nucleotides would then have 9.8 units per turn (Fig. 2). If there is no base pairing, the two strands can be moved relative to one another. We know of no DNA structure of this type, thus we used the approach (see ref. 12) of building molecular models of DNA with these helix parameters and a phosphorus radius of 8.5 Å. (Models with phosphates at a smaller radius[13] would imply an abnormally short phosphorus–phosphorus distance along an fd DNA strand of 26.7 Å pitch and 2.72 Å axial separation.) The best overall fit to the first three DNA layer lines is given by a model that is unexceptional in the conformation of the sugar-phosphate backbone and the tilt of the bases, but other kinds of models (for example, left-handed or Z-DNA) cannot yet be ruled out.

Meridional intensity at 2.72 Å would be predicted for a regular DNA helix with 2.72 Å axial separation between nucleotides. No meridional or near-meridional intensity is observed at this position, but weak near-meridional intensity is observed on a layer line at 3.02 Å, and strong meridional intensity at 3.42 Å (apparently not consistent with a J_2 Bessel function). These are two of the layer lines predicted for a regular helix of 26.7 Å pitch and 2.72 Å unit rise. These observations, taken together with UV dichroism measurements, would be consistent with a tilted-base conformation of the DNA[7], except for the fact that intensity directly on the meridian at 3.42 Å is forbidden for these helix parameters. Thus the bases are not all arranged on a simple helix—many are stacked axially about 3.42 Å apart despite the mean rise per nucleotide of 2.72 Å.

The data can be summarized by identifying three separate clusters of layer lines on the diffraction pattern. The layer lines with a 32-Å repeat are due to coat protein molecules; the layer lines with a 26.7-Å repeat are due to the DNA which, at low resolution, follows a helix of 26.7 Å pitch and 8.5 Å radius; and the 3.42 Å meridional reflection is indicative of base stacking but is not consistent with a regular helix of 2.72 Å rise per nucleotide.

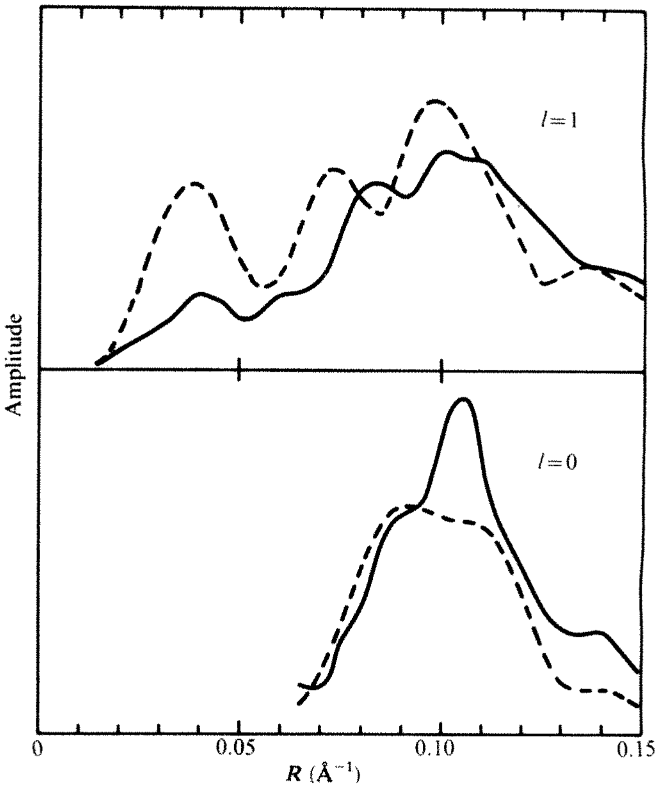

Fig. 4 Distribution of amplitude (absolute values) along layer lines in the strong 10-Å equatorial and near-equatorial region. Observed amplitudes are represented by solid lines, and calculated amplitudes by broken lines. Intensity data were measured[6] from the diffraction pattern shown in Fig. 1. The sharp peak at 0.105 Å^{-1} for $l = 0$ is due to crystalline reflections superposed on the continuous transform. The cylindrically averaged Fourier transform was calculated[6] for the model of Fig. 3. Observed and calculated intensities due to protein were scaled together, using the first seven layer lines, to $R = 0.15$ Å^{-1}. The J_0 Bessel function contribution is not shown. The similarity between the intensity distribution on the fd 32-Å layer lines and the layer lines of Pf1 (ref. 4; Fig. 3) suggests that the coat protein subunit has a similar structure in the two virions. This structure could be either a continuous α-helix rod[10] as shown in Fig. 3, or two α-helix segments occupying roughly the same space in the virion as the continuous rod, but connected in a different way.

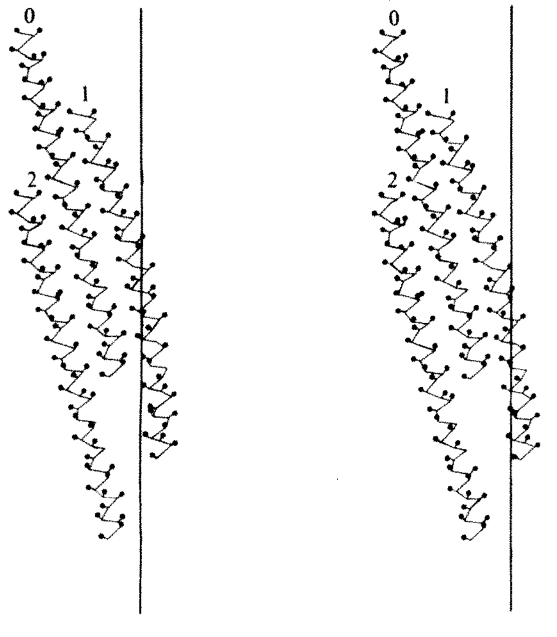

Fig. 3 Stereo pairs showing the interactions between an α-helical subunit and its nearest neighbours in a model of the fd virion fitting the data to 7 Å resolution. The lines connect α-carbons along the sequence. The points represent positions of β-carbon atoms. The view is perpendicular to the virion axis (vertical line) with the N-terminus upwards. These three molecules correspond to the bold lines in Fig. 2.

Structure of TANDEM and its implication for bifunctional intercalation into DNA

Quinoxaline antibiotics (Fig. 1*a, b*) form a useful group of compounds for the study of drug–nucleic acid interactions[1,2]. They consist of a cross-bridged cyclic octadepsipeptide, variously modified, bearing two quinoxaline chromophores. These antibiotics intercalate bifunctionally into DNA[2,3] probably via the narrow groove, forming a complex in which, most probably, two base pairs are sandwiched between the chromophores[4,5]. Depending on the nature of their sulphur-containing cross-bridge and modifications to their amino acid side chains, they display characteristic patterns of nucleotide sequence selectivity when binding to DNAs of different base composition and to synthetic polydeoxynucleotides[4,6,7]. This specificity has been tentatively ascribed to specific hydrogen-bonding interactions between functional groups in the DNA and complementary moieties on the peptide ring[2,4,5]. Variations in selectivity have been attributed both to changes in the conformation of the peptide backbone[6] and to modifications of the cross-bridge[7]. These suggestions were made, however, in the absence of firm knowledge about the three-dimensional structure and conformation of the antibiotic molecules. We now report the X-ray structure analysis of the synthetic analogue of the antibiotic triostin A, TANDEM (des-*N*-tetramethyl triostin A) (Fig. 1*c*), which binds preferentially to alternating adenine–thymine sequences[7]. The X-ray structure provides a starting point for exploring the origin of this specificity and suggests possible models for the binding of other members of the quinoxaline series.

Hydrated crystals of TANDEM, $C_{46}H_{54}N_{12}O_{12}S_2.12H_2O$, were obtained from a mixture of dimethyl formamide/ethanol/water. Crystal data: orthorhombic, $P2_12_12_1$, $Z=4$, $a=18.400$, $b=22.126$, $c=16.435$ Å. Diffractometer measurements for 5,422 independent reflections were obtained with MoKα radiation to a resolution of 0.85 Å at 7 ± 1 °C. The structure was solved with some difficulty by a combination of direct methods and a novel iterative Fourier procedure[8]. Refinement, with all non-hydrogen atoms anisotropic, converged at $R=14.7\%$ for 4,111 data with $F>2\sigma(F)$. Full details will be published elsewhere.

Figure 2 shows the molecular structure of TANDEM. The octadepsipeptide ring is held in a relatively rigid conformation through intramolecular hydrogen bonds NH(L-Val)... O(L-Ala). The quinoxaline chromophores and the disulphide cross-bridge project on opposite sides of the peptide ring. The carbonyl groups of L-Cys and L-Val also project from the side opposite to the chromophores. The molecule displays a helical twist and has an approximate 2-fold axis of symmetry. Bond lengths and angles fall within the normal ranges.

The mean planes of the two chromophores are inclined at an angle of 14°. The distance between the Ser α-carbon atoms is 12.2 Å. Assuming that the intercalated complex is of the Fuller-Waring type[9], with minimal distortion from a classical B-DNA helix, we would expect the chromophore planes to lie parallel, approximately orthogonal to a line joining the Ser α-carbon atoms and separated by a perpendicular distance of 10–11 Å, to allow for bifunctional intercalation[10]. These geometrical constraints are readily imposed on the molecule derived from the X-ray analysis by rotations of approximately 20° about the C_α–N bonds of D-Ser. Such rotations do not result in steric hindrance with neighbouring groups[5,11]. The resultant structure (Fig. 3) can be fitted into the narrow groove of a B-DNA helix,

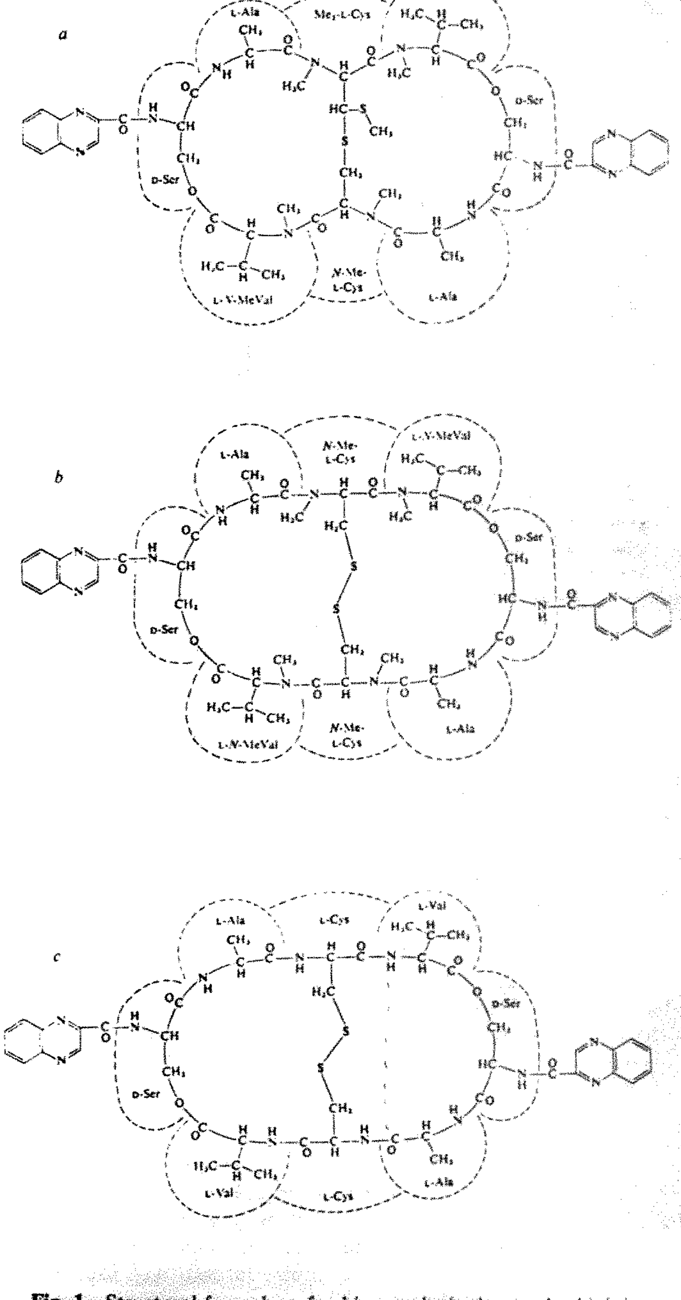

Fig. 1 Structural formulae of echinomycin (quinomycin A) (*a*), triostin A (*b*), TANDEM (des-*N*-tetramethyl triostin A) (*c*).

0028-0836/81/090817—03$01.00

which is known from solution experiments to be unwound by 45.5° on intercalation of TANDEM[2,7] (based on an unwinding angle of 26° for ethidium[12]). In this bis-intercalated model the disulphide cross-bridge projects outwards away from the helix, two base pairs are sandwiched between the chromophores and various functional groups of the cyclic peptide are placed in the vicinity of potential hydrogen-bonding sites on the DNA bases. The pseudo-2-fold axis of TANDEM is aligned with the 2-fold axis between the base pairs (Fig. 4).

Binding experiments with DNAs of varying base composition and with synthetic polydeoxynucleotides have revealed that TANDEM binds at least 7,500 times more tightly to poly(dA-dT) than to poly(dG-dC) and there are marked differences in the binding constants for DNAs of different nucleotide composition[7]. This specificity might be explainable in terms of hydrogen bonding between the peptide backbone of the drug and the DNA bases, using the model derived from the X-ray structure.

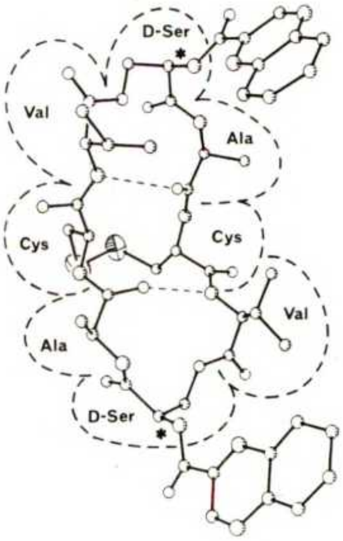

Fig. 2 Molecular structure of TANDEM determined by X-ray analysis at room temperature to a resolution of 0.85 Å. Dotted lines indicate intramolecular hydrogen bonds between the NH groups of L-Val and the O atoms of L-Ala. These bonds hold the molecule in a relatively stable conformation. Asterisks indicate the N–C$_\alpha$ (D-Ser) bonds through which the chromophores are attached to the octapeptide ring.

There are two potential hydrogen-bond donors and one potential acceptor in each half of the molecule (Fig. 3) which could be directed towards the interior of the helix on intercalation. The donors are the NH groups of L-Ala and D-Ser and the acceptors are the carbonyl O atoms of L-Ala. The latter are already involved in an intramolecular H bond with the NH group of L-Val (Fig. 2) and in an unfavourable position to accept a second hydrogen bond from the available donors of the DNA base pairs. Of the potential donor groups of TANDEM the NH groups of L-Ala seem to be well placed, as planes parallel to the chromophores oriented as in Fig. 3 and passing through these N atoms are separated by a perpendicular distance of 3.5–4 Å. In the intercalated complex, therefore, the NH groups of L-Ala lie co-planar with the sandwiched base pairs. Experiments with CPK models indicate that a reasonable fit can be obtained with hydrogen bonds of ~3 Å between the NH groups of L-Ala and the O-2 atoms of thymine in the narrow groove (Fig. 4). In this intercalated model an ApT sequence is sandwiched between the chromophores. The unwinding angle, spread over four base pairs, is 40°–50°, consistent with the experimentally determined value for DNA[2,7]. Attempts to build alternative intercalated models involving the N-3 atoms of adenine or the NH groups of D-Ser in hydrogen bonding were unsuccessful, nor could we achieve satisfactory intercalation via the major groove. It is known that binding of the related antibiotic, echinomycin, to phage T2DNA is not prevented by the presence of bulky sugar substituents which occlude the wide groove of the helix[4].

The X-ray structure of TANDEM prompts some suggestions about the character of the intercalation process. Interestingly, the isolated chromophore, quinoxaline-2-carboxamide, unlike simple monofunctional intercalators, shows no detectable interaction with DNA and does not affect the supercoiling of circular DNA[4,10]. Thus, the driving force for intercalation cannot be ascribed simply to a tendency to form stacking interactions between the chromophores and base pairs. In TANDEM, as shown by the crystal structure, the chromophores are held at the approximate position required for bifunctional intercalation by the relatively rigid depsipeptide backbone, and thus a very important geometrical constraint is already 'locked into' the structure of the ligand molecule. Moreover, all but two of the carbonyl O atoms are directed away from the chromophore side of the drug, where they are best placed to retain their hydrogen-bonding interactions with the surrounding solvent after binding to DNA. Such interactions are apparent in the present crystal structure where all but two of the carbonyl oxygens make at least one hydrogen bond with the surrounding water molecules and there is no direct hydrogen bonding between neighbouring TANDEM molecules. The hydration spheres are even more perfect in a structure of TANDEM determined at −135 °C (D. van der Helm, personal communication).

The naturally occurring antibiotics echinomycin and triostin A (Fig. 1*a*, *b*) display patterns of selectivity in binding to DNA and synthetic polydeoxynucleotides which, while characteristic for each antibiotic, are quite different from the marked preference of TANDEM for A + T-rich sequences[2,6,7]. For instance, echinomycin binds well to poly(dG-dC), approximately twice as strongly as it binds to poly(dA-dT), whereas the converse is true of triostin A. These differences from TANDEM are probably

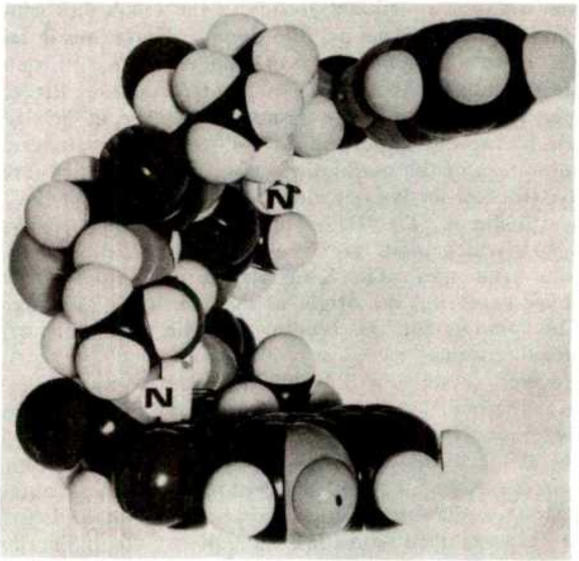

Fig. 3 CPK model of the TANDEM molecule with the quinoxaline chromophores rotated about the N–C$_\alpha$ (D-Ser) bonds from the crystal position to allow for bifunctional intercalation. The rotation is about 20° for each chromophore. The nitrogen atoms of L-Ala donating hydrogen bonds to the O-2 atoms of the thymine bases are indicated.

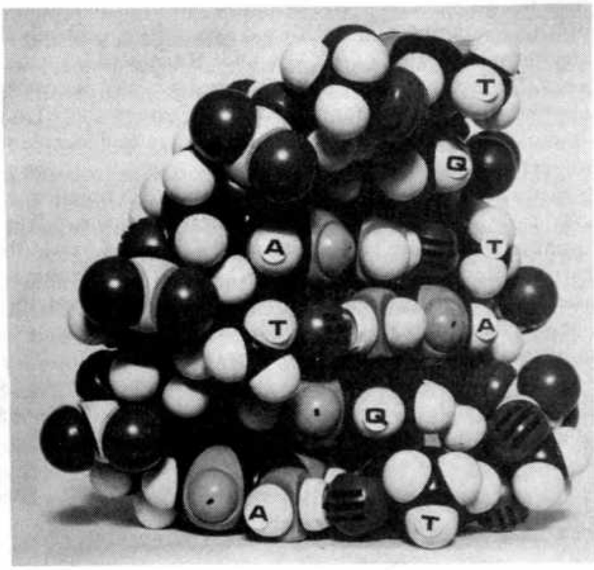

Fig. 4 CPK model of the intercalated complex between TANDEM and a partially unwound B-DNA helix showing the major groove side. The quinoxaline groups (Q) and the bases (adenine, A, and thymine, T) are labelled.

related to the effects of *N*-methylation on the precise conformation of the octapeptide ring and thus the availability of its functional groups for hydrogen bonding[2,4,5,13]. *N*-methylation of the L-Cys and L-Val residues in the natural antibiotics precludes formation of the intramolecular H bonds observed in TANDEM. Moreover, methylation of the L-Val residues necessarily results in conformational differences which will cause the carbonyl oxygens of L-Ala to project in the same direction as the chromophores. From this position they become available as effective hydrogen-bond acceptors for interaction with donors in the minor groove, that is, the 2-amino groups of guanine nucleotides, which may explain the ability of the antibiotics to bind to sequences containing G.C as well as A.T base pairs.

Extrapolation from the crystal structure of TANDEM to detailed molecular models for quinoxaline antibiotic–DNA complexes must be approached very cautiously. Although various lines of evidence (NMR[5,13], conformational calculations[5,11]) suggest that the peptide backbone in all these compounds adopts a relatively rigid and well defined conformation, there is no experimental evidence that this conformation does not alter on intercalation. Indeed, the significant differences found between the present room-temperature X-ray study and the similar one at −135 °C indicate that the orientation of some bonds, particularly those involving carbonyl groups, can be significantly affected by hydrogen bonding to solvent molecules[14]. There is also a degree of uncertainty about local DNA conformation[15,16] and about the orientation of the base pairs with respect to the helix axis in solution[17–19]. The recent X-ray study of the daunomycin–hexadeoxynucleotide complex[20] has shown that widespread changes can occur in the conformation of the backbone and the positioning of the bases on intercalation. Thus, although the present study gives well defined information about TANDEM itself, only a generalized model can be put forward for the DNA-drug complex. We are continuing our attempts to co-crystallize TANDEM with synthetic A-T deoxyoligonucleotides in the hope of establishing the structure of an intercalated complex directly by X-ray analysis.

We thank the MRC and the Cancer Research Campaign for financial support, the SRC for the diffractometer, the Deutsche Forschungsgemeinschaft for a postdoctoral fellowship (E.E.) and Professor R. A. Raphael for constructive comments. M.A.V. thanks the Department of Science and Technology, India, for financial support.

Transglutaminase modifies the carboxy-terminal intracellular region of HLA-A and -B antigens

Jordan S. Pober* & Jack L. Strominger

The Biological Laboratories, Harvard University, Cambridge,
Massachusetts 02138, USA

The HLA-A and -B antigens, encoded in the major histocompatibility complex, are transmembrane proteins whose carboxy termini project inwards from the cell membrane. The intracellular region of the HLA-B7 antigen is known to include two glutamine residues[1]. We have used guinea pig transglutaminase to show that *in vitro* the enzyme couples amines specifically to glutamine residues in the carboxy-terminal region of the HLA-B7 and -A2 antigens. The specificity of this reaction has an immediate practical significance, but may also have a wider biological interest.

HLA-A and -B antigens contain an invariant extracellular polypeptide subunit (β_2-microglobulin or p12) of molecular weight (MW) 12,000 noncovalently attached to a polymorphic 44,000-MW transmembrane, glycosylated, heavy chain (p44)[2]. The heavy chain has three major regions: a 34,000-MW glycosylated, extracellular amino-terminal segment (p34) that is released from the membrane by papain in a complex with the light chain (p34, 12), a transmembrane hydrophobic segment of about 25 amino acid residues, and an intracellular hydrophilic carboxy-terminal region of about 30 amino acid residues[3]. Interactions of the HLA-A and -B antigens with intracellular

constituents must involve the carboxy-terminal intracellular domain.

Transglutaminases are ubiquitous enzymes that catalyse the exchange of the γ-carboxamide ammonia group of a protein glutamine residue within a flexible region of polypeptide for an exogenous primary amine[4]. As shown in Fig. 1, guinea pig liver transglutaminase catalyses the insertion of ^{3}H-putrescine into the heavy chain of HLA-B7 antigen. Similar results were found with HLA-A2 antigen. When dansyl cadaverine was substituted for putrescine, the HLA-B7 or -A2 heavy chain became fluorescently labelled. Neither amine was incorporated into β_2-microglobulin (the HLA light chain). The location of the probe in the HLA heavy chain was ascertained by limited proteolysis. Papain cleaves native HLA-B7 antigen in detergent solution in a stepwise fashion, releasing first the carboxy-terminal hydrophilic region and then the penultimate hydrophobic region, altering the apparent MW of the heavy chain from 44,000 to 39,000 to 34,000 (ref. 3). As shown in Fig. 2, ^{3}H-putrescine radioactivity is released concomitantly with release of the intracellular carboxy-terminal domain. Thus the glutamine residue(s) that is modified must be one or both of those located within this region. Note that none of the 16 glutamine residues in the extracellular region seems to be modified. Therefore, only the intracellular hydrophilic region contains exposed glutamine residues in a flexible portion of the molecule.

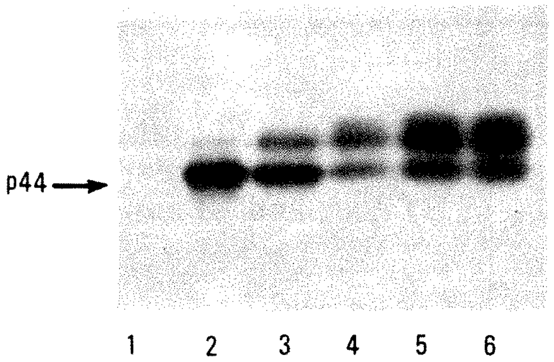

Fig. 1 Transglutaminase modification of HLA-B7. HLA-B7 antigen was purified from the membranes of JY lymphoblastoid cell membranes (doubly homozygous HLA-A2, -B7) by use of allospecific monoclonal antibody immunoaffinity chromatography in a modification (to be published elsewhere) of the procedure of Parham[9]. The pure antigen was adjusted to a concentration of 250 μg protein ml^{-1} in 10 mM Tris-HCl pH 8.0, 0.5% Nonidet P40 (NP40) non-ionic detergent. Guinea pig liver transglutaminase[10] at 50 μg ml^{-1} was pre-equilibrated in a solution made 500 mM in Tris-HCl pH 8.0, 0.5 mM putrescine, 40 mM CaCl$_2$ and 10 mM dithiothreitol at 37 °C for 30 min. This enzyme mixture (0.5 ml) and 0.5 ml of ^{3}H-putrescine-HCl in H$_2$O (0.5 mCi, NEN) were added to 1 ml of the HLA-B7 solution and the reaction was allowed to proceed at 37 °C. At different time points, 100-μl aliquots were withdrawn, placed on ice and made 25 mM in EDTA to inhibit the enzyme. Trichloroacetic acid (50 μl of 50%) was added to precipitate the protein. The precipitates were collected by centrifugation 1 h after the last time point was taken and were washed once with acetone to remove excess trichloroacetic acid. Each sample was dissolved in SDS sample buffer, subjected to SDS-polyacrylamide gel electrophoresis on a 20-cm 7–15% linear gradient with the buffer system of Laemmli[11], and analysed by Coomassie blue staining (not shown) and by fluorography[12]. Lanes 1–6 show the fluorograph of ^{3}H-putrescine radioactivity in the position of the HLA-B7 heavy chain after 30 s, 15, 30, 60, 120 and 180 min of transglutaminase-catalysed modification, respectively. Note that as labelling continues, a portion of the heavy chain shifts its electrophoretic mobility to one of slightly higher molecular weight. The explanation for this shift with time of incubation is unclear.

These results have two additional implications. First, exogenous transglutaminase may be used to modify specifically the carboxy-terminal region of HLA-A and -B antigens for various purposes. For example, spectroscopic probes[5] may be inserted to study the structure and function of this region of the HLA-A and -B molecules. HLA-A and -B antigens may be fluorescently or radioactively labelled, in a manner that does not perturb the antigenicity of the extracellular portion, for use in functional or binding assays with receptors for these antigens. Transglutaminase may be used as a vectorial label[6] to assess whether the carboxy-terminal region of the HLA-A and -B antigen is exposed in a reconstituted liposome preparation. Second, these data are consistent with the possibility that intrinsic transglutaminases could be involved in membrane events, including receptor-mediated uptake[7] and response to mitogenic lectins[8], by catalysis of the cross-linking of the intracellular portion of a transmembrane protein to other intracellular constituents. Labelling of HLA-A and -B antigens (or any other membrane proteins) in intact or broken peripheral blood lymphocytes or lymphoblastoid cells incubated with ^{3}H-putrescine or dansyl cadaverine has not been detected (J. P. and B. Guild, unpublished observations), but suitable conditions may not have been used. However, the data presented here establish that one

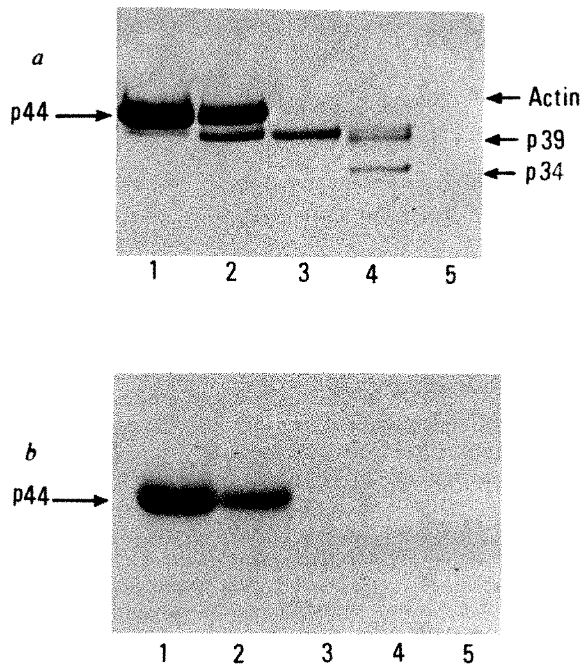

Fig. 2 Limited proteolysis of ^{3}H-putrescine-labelled HLA-B7. HLA-B7 antigen, labelled for 180 min as in Fig. 1 by transglutaminase-catalysed insertion of putrescine into the HLA heavy chain, was subjected to limited proteolysis by papain (Worthington). To 100-μl aliquots of HLA-B7 solution (at 125 μg ml^{-1}), in 100 mM Tris-H Cl pH 8.0, 25 mM EDTA, 10 mM CaCl$_2$, 2.5 mM dithiothreitol and 10 mM putrescine, 10 μl of papain were added and the solution was incubated for 1 h at 37 °C. The reaction was stopped by transfer to ice and by addition of 10 mM iodoacetic acid. The samples were trichloroacetic acid-precipitated and prepared for electrophoresis as in Fig. 1 legend. In this experiment an 8-cm 12.5% acrylamide gel was used with the buffer system of Laemmli[11]. Lanes 1–4 represent proteolysis by 0, 0.2, 1 and 5 μg of papain, respectively. Lane 5 is a rabbit skeletal muscle actin standard. *a* Shows the gel stained with Coomassie blue and *b* is a fluorograph of the same gel. Note that ^{3}H-putrescine label was excised concomitantly with release of the intracellular, hydrophilic portion of the HLA-B7 heavy chain as p44 was converted to p39.

common membrane protein in its intracellular domain is a suitable substrate for transglutaminase-catalysed reactions.

(1→3)-β-D-Glucan (callose) is a probable intermediate in biosynthesis of cellulose of cotton fibres

H. Meier, L. Buchs, A. J. Buchala & T. Homewood

Institut de Biologie végétale et de Phytochimie,
Université de Fribourg, CH 1700 Fribourg, Switzerland

The biosynthetic pathway of cellulose in higher plants is unknown[1]. Attempts to produce cellulose *in vitro* have shown that mainly (1→3)-β-D-glucan (callose) is produced from particulate enzyme fractions of higher plants and uridine diphosphate glucose (UDPG)[2–5]. Some authors have claimed that in certain conditions, (1→4)-β-D-glucosidic linkages were also formed[6–10]. However, there is no conclusive evidence for the formation of pure (1→4)-β-D-glucans from UDPG. As callose forms naturally not only in various parts of plants (sieve and pollen tubes, root hairs, cell plates) but also in response to wounding, it seems best to study cellulose biosynthesis *in vivo* rather than in wounded cells or cell homogenates which might produce callose but not cellulose. Using intact cotton fibres, we have now shown by pulse-chase experiments that callose has a high turnover and is likely to be an intermediate in cellulose biosynthesis at the stage of secondary wall formation.

Naturally grown cotton fibres contain large quantities of callose[11–13]. In the fibres of one ovule of *Gossypium arboreum*, at the onset of secondary wall formation (about 25 days after anthesis), ~1 mg of callose is present out of a total fibre wall weight of ~13 mg. Using two experimental systems, we have investigated the incorporation of ^{14}C-labelled compounds into the cell wall polysaccharides of intact seed hairs of cotton (*Gossypium arboreum* L.). In the first system, whole fruit capsules received, through the cut surface of the petiole, a pulse of [U-^{14}C]sucrose (for about 20 min) followed by a chase with unlabelled sucrose for periods of up to 40 h (Fig. 1 legend). Six capsules, collected about 35 days after anthesis (at the stage of secondary wall formation), were treated in this way. At various intervals they were opened quickly and the intact seed clusters were immediately immersed in boiling 80% (v/v) methanol to avoid possible formation of wound callose. The fibres were isolated, further extracted with hot 80% methanol to remove low-molecular weight substances, and the methanol extracts combined; the fibres were finally homogenized. The radioactivity in the 80% methanol-soluble fraction was mainly contained in sucrose and may be taken to indicate the size of the low-molecular weight precursor pool at the time of analysis. The radioactivity in aliquots of the fibres was counted and other aliquots were treated with dimethyl sulphoxide (DMSO) to extract non-cellulosic high-molecular weight material[14]. The radioactivity in the latter and in the residues was measured. When the DMSO-soluble high-molecular weight material was hydrolysed, glucose was the chief product and the only labelled sugar obtained, although small amounts of unlabelled galactose, arabinose and xylose were detected. Methylation studies and radio gas chromatography, as well as degradation with exo-(1→3)-β-glucanase (EC 3.2.1.58) from *Basidiomycete* sp. QM 806, showed that the labelled glucan in the DMSO extract was of the (1→3)-β-type (callose-type) with a few (1→6)-linkages (our unpublished results). Further treatment of the residual fibre homogenate after DMSO extraction with the exo-(1→3)-β-glucanase gave only very minor amounts of glucose, indicating that with DMSO essentially all the (1→3)-β-D-glucan had been

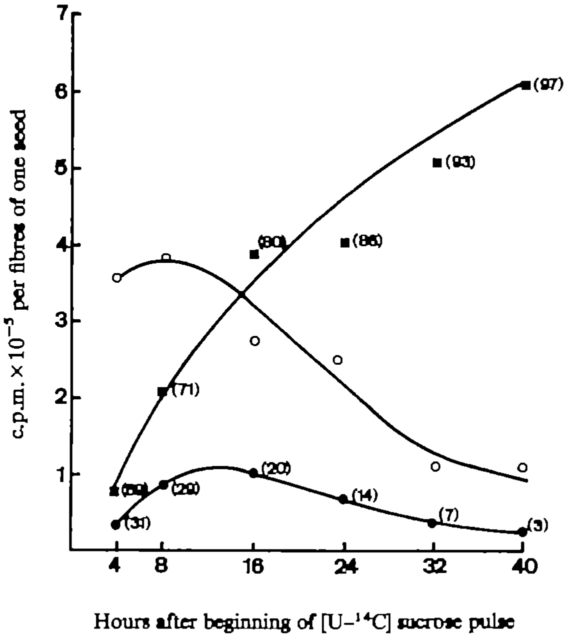

Fig. 1 Pulse-chase feeding of sucrose to petioles of fruit capsules of *Gossypium arboreum* L. The capsules were harvested 35 days post-anthesis (stage of secondary wall formation). The pulse of [U-^{14}C]sucrose (20 μl, 1 mM, 1.85 MBq) was applied through the cut ends of the petioles for about 20 min. The chase was with unlabelled sucrose (~50 μl h^{-1}, 1 mM) in the dark at 30 °C. After different incubation periods the radioactivity was measured in the 80% methanol-soluble fraction (○), the DMSO-soluble fraction, that is, (1→3)-β-D-glucan (callose) (●), and the residue, (1→4)-β-D-glucan (cellulose) (■), of the fibres. Numbers in parentheses are the percent radioactivity in callose- and cellulose-type glucans, respectively.

removed. No degradation was detected on treatment with lichenase (from *Bacillus subtilis*), α- or β-amylase, thereby excluding the possibility of the presence of other non-cellulosic glucans known to be present in higher plants. Acetolysis of the residue gave the peracetate derivatives of glucose, cellobiose and higher cellooligosaccharides. The cellobiose octaacetate was obtained in about 20% yield and such a value is usually taken to indicate that the polysaccharide in question is cellulose. This product was characterized by melting point, mixed melting point and TLC, and its specific activity, which was the same as that of the fibre residue, remained constant on recrystallization. These results show that the radioactivity of the fibre residue is essentially confined to cellulose.

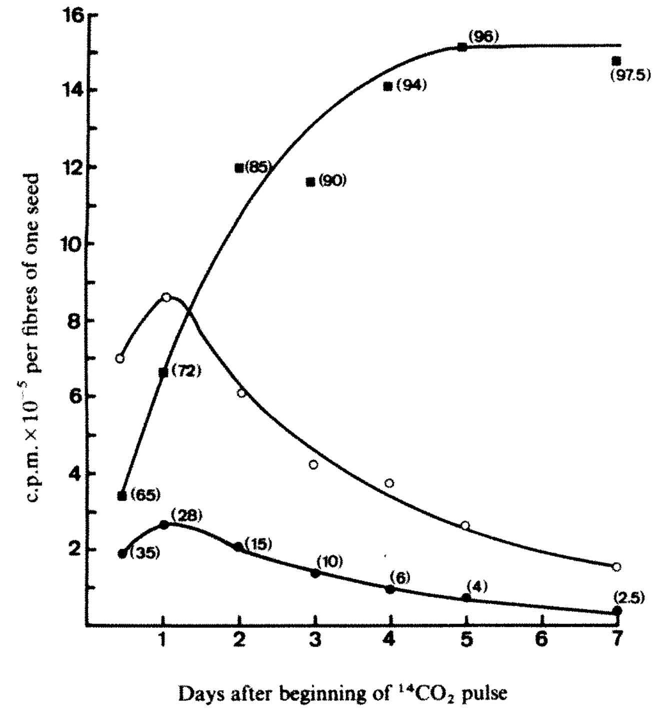

Fig. 2 Pulse-chase feeding of $^{14}CO_2$ to branches of intact plants of *Gossypium arboreum* L. $^{14}CO_2$ (7.4 MBq) was fed in the morning in bright sunlight to branches, each with three or four leaves and one capsule at 35–40 days post-anthesis, inside polythene bags. After 30 min about 80% of the original radioactivity in the bags had been taken up by the branches which were, however, left inside the bags for another 90 min. The latter were then removed and the plants were left in normal day and night conditions, when photosynthesis could occur normally, until the capsules were harvested. The radioactivity was determined in the 80% methanol-soluble fractions (○), the (1→3)-β-D-glucan (callose) (●) and the (1→4)-β-D-glucan (cellulose) (■) fractions of the fibres. Numbers in parenthesis are the percent radioactivity in the callose- and cellulose-type glucans, respectively.

Figure 1 shows that 4 h after the beginning of the pulse a high proportion (31%) of the radioactivity in cell wall glucans is confined to callose. The total radioactivity in the callose increased for about 16 h and then decreased continuously whereas the radioactivity in the cellulose continued to increase. A turnover of callose is evident; its radioactive content decreased from 100,000 c.p.m. in the fibres of one seed to 20,000 c.p.m. between 16 and 40 h after the pulse, while in the same period the radioactivity in the cellulose increased from about 400,000 to 600,000 c.p.m. This larger increase in the radioactive content of the cellulose is readily explained by the fact that 16 h after the pulse, there were still 280,000 c.p.m. in the fibres of one seed confined to low-molecular weight precursors (methanol extract). The apparent turnover of callose is relatively slow but this may be due to the slow replacement of radioactive sucrose by the unlabelled sucrose during the chase, or to the time delay in the arrival of sucrose to different fibres on different seeds in the capsule.

In the second system, $^{14}CO_2$ was given for about 2 h to branches of intact cotton plants with one capsule per branch. This seems to be the most natural experimental system in which abnormal wound reactions would be excluded. In this system also (Fig. 2), within a relatively short time after the pulse a high proportion (35%) of the 80% methanol-insoluble radioactivity of the fibres was in callose. The absolute radioactive content of the callose increased until about 1 day after the pulse and then decreased, whereas that of the cellulose continued to increase. The radioactivity in callose relative to that in cellulose decreased throughout the experiment. The radioactivity in the 80% methanol-soluble low-molecular weight substances of the fibres reached its maximum about 1 day after the beginning of the pulse and decreased thereafter. These results also indicate a turnover of callose and the probable incorporation of its glucose residues into cellulose.

A sharp chase with the nonradioactive compound was impossible with either of the two systems because of the time lag necessary for the entry of the chase substance into the fibre pool and because a certain amount of radioactive precursor continued to enter the fibre precursor pool from other parts of the fruit capsule. It is therefore feasible that the apparent rate of decrease in the radioactivity of the callose during the chase is lower than the apparent rate of increase in the radioactivity of the cellulose even if callose is an obligatory precursor for cellulose. Although our results, in contrast to those of Maltby *et al.*[15], indicate a clear turnover of callose, they do not show whether or not callose is a direct glucosyl donor for cellulose. If this is the case, a (1→3)-β-D-glucan:(1→4)-β-D-glucan glucosyl transferase (transglucosylase) would probably be involved in cellulose synthesis. (1→3)-β-D-Glucanases are undoubtedly present in cotton fibres (unpublished results) and we are now investigating whether, in certain conditions, they can act as transglucosylases.

Suggestions that callose is a cellulose precursor are not new and have been made by several plant cytologists[16–18]. Waterkeyn (personal communication) showed by fluorescence microscopy, after staining with aniline blue, that at different stages of secondary wall formation, cotton fibres always contain a thin layer of a substance reacting like callose at the inner side of the wall. If further studies confirm the precursor role of callose for cellulose in cotton fibres as well as in other cell types, it could be argued that callose may accumulate where the biosynthetic step from callose to cellulose is inhibited.

MATTERS ARISING

Allez Neanderthal

APSIMON[1] concluded that Lévêque and Vandermeersch's discovery of a Neanderthal specimen at Saint-Césaire associated with Châtelperronian denies a Neanderthal ancestry for modern Europeans. In reality, taking account of other evidence a completely different conclusion may be drawn from this critical discovery.

The following points are relevant. (1) Robust but modern (although not European) populations are associated with Mousterian (Middle Palaeolithic) industries in the Levant[2,3]. (2) Neanderthal (or Neanderthal-like) remains are associated with Aurignacian (Upper Palaeolithic) in Croatia[4–6]. (3) Evolutionary trends in the European Neanderthals themselves (*contra*[7]) are clearly in the direction of modern Europeans[6,8]. (4) The earliest modern Europeans (earlier than Cro-Magnon) are distinctly Neanderthal-like in their morphology[5,8–10].

The evolutionary hypothesis is supported by the backward extension of trends in the modern Europeans (the samples become distinctly more Neanderthal-like earlier in time) and the forward extension of trends in the Neanderthals of Europe (they become distinctly more like modern Europeans later in time). In this regard, Saint-Césaire specifically resembles the late (more modern) Neanderthals from Vindija cave[4–6] and thus provides important support for the observed trends within the Neanderthal sample.

The *average* changes between late Neanderthals and early modern Europeans should not be confused with the comparison of La Chapelle and the Cro-Magnon male. Such changes could happen fairly quickly, responding to changes in skeletal stress during growth[11] and changes in selection[5]. If migration played an important role, the origin of the migrating populations with their distinctive European features remains unknown. If the Levant is considered to be the place of origin, in spite of the lack of morphological relations, the resulting juxtapositions of hominids and industries makes nonsense of virtually every previous hypothesis of archaeological or morphological sequence.

APSIMON REPLIES TO WOLPOFF—We are in agreement about point (1). Concerning point (2): The relevant hominid finds (from Vindija, layer G_1) are described as 'non-diagnostic morphologically' and could be Neanderthal or early *sapiens*, the lithic artefacts from the layer are not diagnostic, but the single split-based bone point is consistent with 'Aurignacian'. There is, however, no intrinsic improbability about Neanderthal—Aurignacian association. I agree with points (3) and (4). Analyses which bring together in one sample all classic European Neanderthal crania and in another sample all European Upper Palaeolithic crania (including some specimens now considered to be Mesolithic) obscure this. The recently described Neanderthal frontal bone from Hahnöfersand near Hamburg[1], dated to ~36,000 BP, which has been considered as indicating hybridization with *sapiens*, might equally well be cited as a further example of this evolutionary trend.

In general, the hypotheses presented by Wolpoff provide an explanation of the Neanderthal-*sapiens* transition in Europe which can be far more easily harmonized with current interpretation of the archaeological evidence than can the hypotheses presented by Stringer *et al.* However, if the archaeologist must pick his way with care through the differing interpretations offered by anthropologists, the latter would be well advised to remember that 'Upper' and 'Middle Palaeolithic', 'Mousterian', 'Aurignacian' and such are artificial constructions, that attempts to attribute artefactual assemblages to one or other category may create impressions of discontinuity where none exists, and that the most useful information to be obtained from artefacts relates to patterns of activity.

1. Bräuer, G. *Archäol. Korresp.* **10,** 1 (1980).

WE are in broad agreement with ApSimon[1] regarding the significance of the Saint-Césaire discovery from France[2], although it must be emphasized that our comments are preliminary in the absence of detailed descriptions of the archaeology and fossil human material. An effect of this discovery will be to focus the 'Neanderthal problem' in Europe to a consideration of events in the period between ~35,000 and 30,000 yr b.p.

The discovery of early Upper Palaeolithic tools in association with a Neanderthal skeleton at Saint-Césaire has apparently confirmed the prediction that the technological transition to the Châtelperronian was accomplished by indigenous populations[3]. It is now plausible that the same kind of association between Neanderthal hominids and industries termed 'early Upper Palaeolithic' applies for other areas in Europe (for example, for the 'leaf-point' industries of northern and central Europe and for the Uluzzian of Italy)[4]. Furthermore, the cultural continuity of these industries (for example, the Châtelperronian) with later Upper Palaeolithic industries (the later Perigordian [Gravettian] for example) has by no means been established because consideration of the subsequent development of these early Upper Palaeolithic industries often reveals the intervening presence of Aurignacian assemblages which are typologically not locally derived. In France there are occurrences of both Châtelperronian and Aurignacian, but during the subsequent Arcy interstadial (~32,000–31,000 yr b.p.) the Châtelperronian disappears[5,6].

ApSimon's claim that there is no reliable evidence for the existence of the Aurignacian complex in central Europe earlier than it occurs in France needs qualification. Although the Tŭrnovo province of Bulgaria is not geographically central in Europe, recent work there at the Bacho Kiro cave is highly germane to a discussion concerning the origin of the Aurignacian in Europe. For this site there is now an internally consistent series of radiocarbon dates which supports the existence of a well defined Aurignacian industry at about 43,000 yr b.p. (Ly-1102, GrN-7569, 7545, 7570) which has no local antecedents. It is claimed that the same stratum is associated with 'primitive' but anatomically modern human remains[7,8]. If we accept these dates from Bacho Kiro it raises the possibility that the Aurignacian there is ancestral to that of central and western Europe. However a postulated east–west diffusion of Aurignacian populations and/or techniques cannot yet be demonstrated with the present precision of the radiocarbon method.

In south-west Asia the critical time period available for an evolutionary transformation or replacement of Neanderthal populations is probably before 40,000 yr b.p., perhaps well before[9]. Thus *the Saint-Césaire find apparently* demonstrates for the first time that

0028-0836/81/090823—02$01.00

Neanderthals in western Europe probably existed at the same date as much more modern-looking populations in south-west Asia (as at Skhūl and Qafzeh) and perhaps in Europe (as at Velika Pećina, Brno, Mladeč (*contra* ApSimon) and Hahnöfersand)[10–16]. No well preserved fossils which are demonstrably intermediate in significant characters between Neanderthals and anatomically modern humans have been described from either of these areas. The fact that some of the earliest anatomically modern hominids in these areas display characters such as robust brow-bridges and large teeth does not necessarily imply that they evolved from Neanderthal ancestors, as such characters are probably merely plesiomorphous (primitive) for *Homo sapiens* generally, and therefore have no phylogenetic relevance in these comparisons. As European and south-west Asian Neanderthals share suites of characters which are apparently autapomorphous (uniquely derived), it is these traits which are significant in any analysis of relationship between Neanderthal and early anatomically modern hominids, as is the presence or absence of traits considered autapomorphous for anatomically modern hominids. With very few exceptions such characters do not cross the morphological division between the Neanderthal and early anatomically modern groups[10–13,17].

The many characters shared between the European and south-west Asian Neanderthals and the many different characters shared between the early anatomically modern fossils of the same two areas mitigates against any evolutionary scheme which posits only *in situ* evolution between Neanderthals and anatomically modern humans in each area[10–13,17]. Evidence now suggests that Eurasian Neanderthals were temperate or cold-adapted forms, whereas the early anatomically modern humans of the same area were not. This implies that a model involving at least some gene flow from outside this area at the time of the first appearance of anatomically modern humans is more appropriate[18].

Thus we agree with ApSimon that, pending further description, the Saint-Césaire Neanderthal disproves the idea of an *in situ* hominid transformation in Europe at a Mousterian/Upper Palaeolithic interface. Instead, the polyphyletic origins of the Upper Palaeolithic in Europe may be matched by a dichotomy, at least, in the morphology of the hominids that produced it. The wealth of new evidence that is now accumulating, together with the promise of a more reliable chronological framework, will allow us to monitor more precisely the events of this key period in prehistory. We would also argue that more sophisticated models are needed than those which posit either mass extinction, hybridization or rapid *in situ* evolution of Neanderthal hominids at the time of the appearance of anatomically modern humans in Europe.

APSIMON REPLIES TO STRINGER *ET AL.*—Concerning Bacho Kiro: If the industry corresponds to accepted definitions of 'Aurignacian', 43,000 BP would be a surprising date, as it would be ~10,000 yr older than dates obtained elsewhere.

We can agree that Velika Pécina, Brno and Mladeč may be of the same order of age as Saint-Césaire, subject to the uncertainties of present chronologies, but not that they might be substantially older, as was implied by the traditional interpretation of Würm I-II-III in central Europe.

I do not believe that the case has yet been made for the previous evolution of the Aurignacian. Interstratification of Aurignacian and Châtelperronian raises the possibility that they are functionally differentiated variants of the same tradition. Blade technology is not substantially more important in these early European 'Upper Palaeolithic' industries than in some Mousterian industries and development from the Mousterian lithic tradition seems to be their most likely origin.

ARTHUR APSIMON
Department of Archaeology,
University of Southampton,
Southampton SO9 5NH, UK

Why do jackals help their parents?

BLACK-BACKED jackals (*Canis mesomelas*) sometimes stay with their parents and help them raise subsequent litters. Based on a positive correlation between the number of pups surviving in a litter and the number of adults (parents plus helpers) in the family unit, Moehlman[1] concluded that pup survivorship is enhanced by the presence of helpers. Unfortunately, her analysis contains errors of calculation and interpretation that seriously weaken this conclusion. Here I correct those errors and present an alternative explanation for her results.

First, an error in the calculation of the correlation coefficient (between 'pups surviving' and 'number of helpers') markedly inflates the statistical significance of the result. From the data shown in Moehlman's Fig. 1, I calculate $R_s = 0.58$ (Spearman rank correlation coefficient; $P < 0.05$) and not $R_s = 0.967$ ($P < 0.01$) as reported. Although the correlation coefficient is still statistically significant, factors other than the number of jackal helpers in a family unit obviously contribute substantially to the observed variation in the number of pups that are raised from a litter.

Second, it is stated[1] that "an adult helper gains more (yield 1 pup per adult) by being a helper of its parents than by finding a mate and raising its own pups aided only by its mate (yield $\frac{1}{2}$ pup per adult)." For both parents and helpers, however, the relevant measure of reproductive success is the total number of pups that survive from a litter, and not the number that survive per adult. As long as a helper's parents stay mated, the coefficients of relatedness between the helper and its siblings in subsequent litters, and between the parents and their new offspring, are the same (that is, $r = \frac{1}{2}$). Therefore, a helper realizes the same 'reproductive success' whether helping its parents increase their litter size by n pups or raising n pups itself (with its own mate). The calculation of 'yield per adult' always underestimates the benefit that accrues to helpers when they contribute to the increased reproductive success of their parents. For example, in terms of yield per adult, a jackal seems to increase its reproductive success by only $n/3$ when helping its parents raise an additional n pups, but it increases its reproductive success by $n/2$ by raising its own n pups. In fact, both of these increases in reproductive success should be the same.

Data shown in Moehlman's Fig. 1 can now be used to assess the reproductive consequences of becoming a helper instead of mating. The slope of the geometric mean regression[2] of 'pups surviving' over 'number of helpers' ($y = 0.9 + 1.67x$; $n = 15$) is an estimate of the

0028-0836/81/090824—02$01.00

average increase in reproductive success of a family unit due to the addition of each helper. Thus, each helper adds about 1.7 pups to a litter raised by its family unit. The reproductive success of an adult that finds a mate and raises pups, without any helpers, is, on average, 1.0 pups ($n = 4$). In the short term, then, jackals do seem to gain more (a net gain of $1.7 - 1.0 = 0.7$ pups) by helping their parents than by mating, but these gains must ultimately be weighed against the disadvantages of foregoing both dispersal and mate selection until the family unit breaks up (for example, when one of the parents dies). It is not surprising, therefore, that few jackals remain with their parents for more than 1 yr (ref. 1).

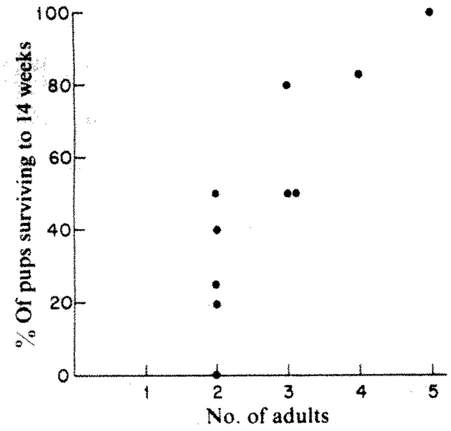

Fig. 1 Number of adults per family and pup survivorship from 3 to 14 weeks ($n = 10$; Spearman rank correlation coefficient, $R_s = 0.88$; $P < 0.01$).

Finally, Moehlman erroneously equates 'number of pups surviving' with 'pup survivorship'. Survivorship means survival rate, and would be an estimate of the average probability of a pup surviving to weaning, but such data are not presented. The litter size of black-backed jackals at parturition varies from one to eight pups[3]. I suggest, therefore, that the positive correlation between the number of helpers and the number of pups raised may not be caused by pup survival rates, but may be the result of higher litter sizes at birth for females that have helpers. Helpers are usually young jackals that have stayed with the family unit from a previous litter[1]. Their continued presence could, therefore, act as a proximate stimulus for their mother to increase litter size, especially as helpers also provide food for the family unit[1]. This pattern should be looked for in other studies of communal breeding systems and may be expected in any species where clutch size varies with food supply. For example, such a response to helpers seems to occur in both the Tasmanian native hen (*Tribonyx mortierii*)[4] and the Puerto Rican Tody (*Todus mexicanus*)[5], where clutch sizes are larger when families have helpers. Jackals may ultimately help their parents because helping increases their inclusive fitness but further work will be needed to determine whether those fitness increases are due to larger litter sizes or increased pup survival.

ROBERT D. MONTGOMERIE

Department of Biology,
Queen's University,
Kingston, Ontario, Canada K7L 3N6

1. Moehlman, P. D. *Nature* **277**, 382–383 (1979).
2. Ricker, W. E. *J. Fish Res. Bd Can.* **30**, 409–434 (1973).
3. Brand, D. J. *Proc. zool. Soc. Lond.* **140**, 617–659 (1963).
4. Ridpath, M. G. *C.S.I.R.O. Wildl. Res.* **17**, 1–118 (1972).
5. Kepler, A. K. *Publ. Nuttall Orn. Club* **16**, 1–190 (1977).

MOEHLMAN REPLIES—Montgomerie is correct in recalculating $R_s = 0.58$ (Spearman rank correlation coefficient; $P < 0.05$). I thank him for his correction; however, I disagree with his alternative explanation, in that he implies it is mutually exclusive.

The correlation coefficient is still significant. Furthermore, litter no. 15 was an aberrant group in which the parents were old[1], only one helper of three was functional throughout the critical period of pup development and one pup survived. This particular helper was also the only example of an individual helping for more than 1 yr. This datum could be shifted to the three-adult column, but for biological reasons I think that it distorts the relationship between presence of helpers and pup survival. If correlation coefficients are calculated for the remaining 14 litters, $R_s = 0.83$ ($P < 0.01$).

The relevant measure of reproductive success is the number of genes surviving. Thus Montgomerie is correct in stating that the important measure is the total number of surviving, related pups. Additional data for three litters were collected in 1978, and on average, in 17 litters: one pair raised 1.3 pups ($n = 6$); one pair + 1 helper raised 3.3 pups ($n = 8$); one pair + 2 helpers raised 4.0 pups ($n = 2$); one pair + 3 helpers raised 6.0 pups ($n = 1$). (The data on litter 15 are not included in these calculations.) Thus, by delaying reproduction for 1 yr, a helper potentially increases its inclusive fitness by on average 1.7 pups, assuming that helping incurred a minimal cost. At present there is controversy as to how to measure 'inclusive fitness' and any suggestions would be appreciated. This, of course, is only one variable, and factors such as increased experience on the natal territory, territorial inheritance and increased survivorship may be equally important (from the helper's point of view). The situation is further complicated by the fact that a 1-year-old jackal can emigrate and still accrue this inclusive fitness as long as a sibling stays and helps. Data on success at emigrating, mating and establishing a territory at 1 yr of age compared with 2 yr of age are needed to answer fully questions concerning kin selection in this study population of black-backed jackals.

Number of adults versus number of live pups at 14 weeks is the critical measure in terms of kin selection and investigating the problem of why jackals help their parents. However, to clarify the relationship between the presence of helpers and pup survival, further data are presented (Fig. 1). Litter size at first emergence from the den (approximately 3 weeks old) is known for 10 of 17 litters. Dens were not disturbed because of the potential detrimental effect on pup survival and subsequent den use (dens may be used again). The mother spends most (90%) of her time in the den during the first 3 weeks, and is fed by her mate and helpers. Data presented in ref. 2 was for pup survival to 14 weeks. As stated, it was during this vulnerable period that mortality was observed. Thereafter, pups no longer used a den and began to forage throughout the home territory. Number of adults versus pup survivorship (3–14 weeks): $n = 10$, $R_s = 0.88$, $P = < 0.01$; number of adults versus pup survival at 14 weeks: $n = 17$, $R_s = 0.85$, $P = < 0.01$; number of adults versus litter size at 3 weeks: $n = 10$, $R_s = 0.83$, $P = < 0.01$; number of pups at 3 versus 14 weeks: $n = 10$, $R_s = 0.68$, $P = < 0.05$.

The highest R_s value is between number of adults and percentage of pups surviving from 3 to 14 weeks. The lowest R_s value is between litter size at 3 weeks and 14 weeks. Information on gestation and prenatal growth in mammals suggests that pup size rather than number of pups will be affected by maternal nutrition, except in cases of prolonged starvation.[3] Litters of dogs raised in the laboratory experience high mortality during the first 3 weeks[1]. Thus information on litter size at 3 weeks may not be a reliable indicator of initial litter size. Helpers may increase initial litter size, but in current data obtained with jackals, the most significant correlation is with pup survivorship from 3 to 14 weeks. Thus it seems reasonable to conclude that helpers improve pup survival rates, possibly from a very early age, and may even affect initial litter size.

Size constancy does not fail below half a degree

AS an observer's distance from an object varies, so does the visual angle subtended by the object at the observer's eye. One of the most reliable phenomena in psychology is that when distance information is available the perceived size of an object is nearly constant despite variations in visual angle, or retinal image size[1]. A corollary is that images of constant visual angle seem to vary in size with perceived distance (Emmert's law). This phenomenon ('size constancy') is only one part of the more general property of perception that one might call 'object constancy', embracing constancy of size, shape, depth, velocity, lightness, colour and so on. A recent report[2] has claimed "that size constancy holds when image size is above half a degree, and breaks down when it is less". The claim, however, was based on demonstrations and anecdotal evidence, rather than experiment. We show experimentally that size constancy in the laboratory is equally good at target sizes above and below $\frac{1}{2}$°.

The targets were single, black, vertical lines 1.2 arc min wide presented at three viewing distances (114, 228 and 456 cm) with four lengths ($\frac{1}{8}$, $\frac{1}{4}$, $\frac{1}{2}$, 1 deg). Each line was fixed in the centre of a white card subtending 5.25° vertically by 3.75° horizontally independent of viewing distance. Each card was placed at the appropriate position on a long laboratory bench on which papers and small objects were scattered. Viewing was binocular with full room lighting. Thus, distance information was abundant, but for a given target size (angle), the length and width of the line and of the frame in which it was set were of constant visual angle, independent of distance. The subject looked back and forth between the target and an oscilloscope screen placed at 228 cm distance, about 6° to the right of the target. His task was to adjust the vertical separation between two small green dots on the screen until the separation 'appeared to match the size of the target'. Trials were presented in random order and the 12 conditions were repeated 3 times for each of the 10 subjects (5 male, 5 female).

The results (Fig. 1) show clearly that perceived length of a line of constant visual angle varies with distance in almost exactly the same way for all target sizes in the range $\frac{1}{8}$°–1°. Analysis of variance not surprisingly showed highly significant effects of both visual angle and viewing distance ($P \ll 0.001$), but most importantly the interaction between distance and visual angle was not significant ($F_{6,29} = 1.47$, $P > 0.10$). If size constancy were weaker or absent below half a degree the slope of the curves in Fig. 1 would be shallower or even flat for small target lengths. Our data strongly contradict any such effect. Constancy was not complete (this would be given by a slope of 1) but it was equally good for all target sizes.

In a second part of the experiment, an electronic flashgun was used to create the afterimage of a line $\frac{1}{4}$° long. The observer viewed the afterimage on a plain white card of constant visual angle at each of the three distances, and made length matches as in the first part of the experiment. A second or third exposure of the line was given if necessary to complete a total of nine trials. One subject reported no afterimage, but the data from the remaining nine (crosses in Fig. 1) were not significantly different from those obtained with a real line of $\frac{1}{4}$° ($F_{1,8} = 0.84$, not significant).

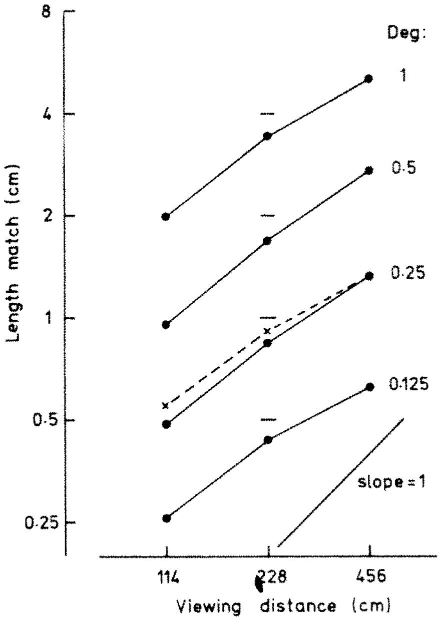

Fig. 1 Solid symbols show results averaged over 10 subjects who adjusted a pair of dots to match the lengths of lines subtending four different visual angles at three viewing distances. Crosses represent similar judgements (nine subjects) made with an afterimage $\frac{1}{4}$° long. Horizontal bars represent the ideal match when target and dots were at the same distance. A slope of 1 would represent perfect constancy, and zero slope would indicate judgements based purely on visual angle (no constancy). The average slope of regression lines fitted to the solid points was 0.70, with no significant interaction between distance and visual angle.

Ross *et al.*[2] reported that afterimages subtending less than $\frac{1}{2}$° did not seem to change size with 'projected' distance, and that the finding was robust in classroom demonstrations. We flashed a 2-cm line to a group of 27 students, all of whom were more than 228 cm distant. The afterimage would thus be less than $\frac{1}{2}$° for all observers. They observed the image on their hands and then on a far wall. None reported no change of size, 19 said the image got bigger when further away, 2 said it got smaller and 6 reported no image. Ross *et al.*[2] also appeal to the reader's direct experience of the breakdown of constancy. Our own experience confirms our classroom demonstration, that small afterimages obey Emmert's law in the usual way. When we acted as subjects in the experiment, our data were virtually identical to those of Fig. 1.

Ross *et al.*[2] remark that objects seen in the distance or from the top of a tall building seem 'small'. It may be that in these cases, and in their Fig. 1, information about the true distance is inadequate, or impoverished by poor resolution of detail. As a result, both distance and size would be underestimated[1]. The fact that many distant objects subtend less than $\frac{1}{2}$° may be quite incidental.

We conclude from our experiments and demonstrations that size constancy for both real targets and afterimages is just as good for small images as for large ones. Indeed, we should suffer very curious distortions in the perceived relative size of objects if this were not so. There seems to be no substance to the claim that size constancy fails below half a degree.

We thank the SRC for financial support.

BOOK REVIEWS

Risk assessed and risk perceived

Eric Ashby

Societal Risk Assessment: How Safe is Safe Enough? Edited by R.C. Schwing and W.A. Albers Jr. Pp.363. (Plenum: 1980.) $29.50, £18.59.

LOOKED at with the naive eye of logic, a calamity killing 10^4 people, likely to occur once every 10^4 years, does not appear different from a calamity killing one person every year. Looked at with the complex eye of human judgement, there is a massive difference. A nuclear melt-down once every ten years, killing half a million people, is a horrifying thought; but that level of carnage is only the linear extrapolation of the average annual death rate on the roads of the United States. This disparity between the statistical assessment of a risk and the personal perception of the risk has important implications for public policy. The cost of making things safe — roads, airlines, nuclear power stations, drugs — rises steeply as the risks are reduced. A level of cost is reached when it would be fantastically expensive to make the thing any safer. So politicians have to ask: How safe is safe enough?

It is not surprising, therefore, that conferences and books on risk-management are cropping up all over the place. They bring together the opinions of statisticians, who can tell you with some confidence what your chances are of being killed on the roads, stifled with emphysema through smoking cigarettes, or struck by lightning; and the opinions of psychologists, who can tell you (with as much confidence, if with less evidence) how you and I evaluate these statistical assessments. And the conferences are attended by policy-makers who go away perplexed and under the obligation to make decisions which will reconcile the disparity between assessed and perceived risks. The disparity remains, but it is encouraging that conferences on risk-management bring to the surface new ideas and fresh attitudes to a problem which has become of major political importance.

Societal Risk Assessment is a record of one of the best recent conferences on the issue. It was arranged by the General Motors Research Laboratories. Let it be said at once that although General Motors might be assumed to have a vested interest in reassuring the public about some kinds of risks, there is no sign of bias in this volume. There are frank discussions of the risks we run and the risks we accept; this section includes an excellent summary of the causes of road accidents, studied in England by a team at the Transport and Road Research Laboratory. The book then goes on to discuss what it costs to reduce risks. Notable among these discussions is a paper from an expert on underwriting in the insurance business. When you come to think of it, insurance underwriters are the one profession who have to try to reconcile assessed and perceived risks; otherwise they would go out of business.

Having discussed what are, and what are not, acceptable risks, and how much society can afford to pay to reduce risks, the conference then went on to tackle an even more controversial question: Who shall decide what risks we are permitted to run? This is a touchy issue among motorists in Britain just now. Despite the alarming casualty figures on the roads of Britain (nearly 7,000 a year killed) the chance of any individual in the whole population being killed is only 1 in 2,500 years. This explains the indifference of the British public toward road accidents. But the problem for society as a whole remains serious: every fatal accident is reckoned to cost some £64,000. It is not disputed that the number of fatal and serious accidents would be reduced if people wore seat belts, drove at not more than 55 miles an hour (as they are obliged to do in many American States), and did not drink alcohol before driving. Is it a duty of the State to compel its citizens to take these precautions? And if so, can the citizens be persuaded by propaganda to come to a consensus about this (after all, there is a consensus about driving on the left-hand side of the road)? Or must they be compelled without having consented? Or, in the name of liberty, should motorists be allowed to endanger themselves (at the taxpayer's expense in a country with a national health service) to their heart's content? The conference did not, of course, come to decisions on these questions; but the issues were thoroughly aired.

The first three sections of the book endorse, with a wealth of fresh examples and neat arguments, conclusions already familiar to those who have studied the subject: for example that there is no such thing as zero risk; that people (including experts) commonly bias their opinions by giving too much weight to the severity of an incident and too little weight to its frequency; that unfamiliar risks, such as hazards from radioactivity and chlorofluorocarbons, generate more anxiety than "classical" risks, such as floods and tornadoes. The last section of the book tackles the consequence of these conclusions, namely that "at the center of the risk problem are people and their fears". Life in affluent Western countries is more secure than it has ever been; yet people are more jittery about hazards than their grandparents ever were. There are still highly educated people who will not sit down to dinner with 13 at the table, and other highly educated people who join expeditions to climb in the Himalayas. The last three papers in the book deal with this fascinating region of social anthropology.

There is already a considerable library of books on risk assessment. Two of the books are outstanding in quality and content. One is the report on the international seminar held in Stockholm in 1978 (*Energy Risk Management*, edited by G.T. Goodman and W.D. Rowe; Academic Press, 1979). The other is *Societal Risk Assessment*. Anyone who has digested these two books can reckon to be up to date in the state of the art of risk management. ☐

R. K. S. Wood

Fungus Diseases of Tropical Crops. By Paul Holliday. Pp.607. (Cambridge University Press: 1980.) £55, $125.

A LARGE proportion of the world's crops are grown in the tropics where they are of two main kinds. First are those with cash products, important in world trade and grown in large units using advanced technologies. Then there are the crops, not always of food, grown in much smaller units by methods still largely traditional and little affected by modern technology. As would be expected, there is substantial research on diseases of the first type of crop, but much less on diseases of the other, although, of course, these diseases are as or more important when they decrease the yields of subsistence foods to tragically low levels. Diseases of food crops in temperate countries may be financially inconvenient; in the tropics they can cause famine.

There are many general texts and

innumerable monographs on diseases of temperate crops — understandably, because most of the world's plant pathologists are in non-tropical countries. In relation to need there are all too few authoritative texts on diseases of tropical crops; the publication of a new and large book on the subject is, therefore, something of an event.

Dr Paul Holliday has been studying and reporting on diseases of tropical crops for about 30 years, many of them as a member of a pool of plant pathologists, spending much of his time in the tropics and the rest of it at the Commonwealth Mycological Institute at Kew. With this background, there was every reason to expect a first-class book from the author, and first class it is.

An introduction describes in detail the plan of the book and its parts, and the main sources of information on taxonomy and nomenclature. There follow, in 556 double-column pages of small but readable type, descriptions of fungal pathogens and the diseases they cause in plants grown as crops in the tropics. The fungi are listed alphabetically by perfect state genera with, occasionally, the omission of entries under the imperfect state genera better known to many plant pathologists. A description of the morphology and more general features of each genus is followed by a list of main references to the genus. For each species, under each genus there is a description of the morphology and a critical reference followed by accounts of the diseases it causes — again accompanied by a list of important references, each including the volume and page or abstract number for an abstract in the *Review of Applied Mycology* or the *Review of Plant Pathology;* this is particularly useful. The accounts are full and remarkably compact for the amount of information they contain. Quite properly, the emphasis is on factors relevant to diseases in the field and on their control. But there are quite adequate references to physiological, biochemical and related research.

There is an excellent appendix of host plants, their major and minor pathogens, and selected references, a list of common and botanical names of host plants and, finally, two indexes of fungi under perfect and conidial state names.

This book presents a huge amount of information accurately, clearly and systematically, is an excellent work of reference and will remain so for many years. The accounts of the diseases are such that they can also be read with pleasure. Expensive though it be, a thousand copies could be bought for the price of one electron microscope and, where most needed, they will be a lot more useful. They will also require little maintenance and last much longer. ☐

Topical tropical meteorology

Reginald Newell

Climate and Weather in the Tropics. By H. Riehl. Pp.611. (Academic: 1979.) £28, $67.50.

STRANGERS to our subject may wonder why the tropics should be accorded a separate treatment in studies of climate and weather. After reading Riehl's book, I suspect that it is the sheer volume of new material available rather than fundamental differences in the characteristic phenomena that prompts this division. Many of the early meteorological studies dealt with the tropics; Trade Winds were analysed for their practical use to shipping, and early ideas about the global general circulation were based (often erroneously) on the tropical Hadley cell circulation.

In the twentieth century, frontal systems and the changing patterns of cyclones and anticyclones began to be explored in depth, both observationally and theoretically, and the focus and excitement switched to middle latitudes. The old ideas of general circulation were replaced by those which gave a pre-eminent role to the large-scale quasi-horizontal eddy processes; theoretical work by Jeffreys was followed by observational studies by Bjerknes, Priestley, and Starr and his colleagues. Most of the observational data came from the middle and high latitudes of the Northern Hemisphere. During and after the Second World War, forecasters from middle latitudes had to ply their trade in the tropics and many tried to translate ideas about middle-latitude systems to those of the tropics, without success. In fact, when data on the general circulation of the tropics became available it was realized that the quasi-steady Hadley cell circulation and the associated Walker circulations in longitudinal planes dominate the tropics, while the eddy processes govern the general circulation of middle latitudes.

There are of course some major differences between the regions: the rather flat surfaces of constant potential temperature in the tropics compared to the steep slopes — the strong baroclinicity — of middle latitudes; the easterly jet streams rather than the westerly jets of middle latitudes; the presence of a two-year cycle, with a shift from east to west, in the zonal winds of the tropical lower stratosphere as compared with the one-year seasonal cycle of middle and high latitudes; the large extent of tropical warm ocean, with temperatures greater than about 300 K, which seems to be necessary to spawn and maintain hurricanes; the mean vertical motions which in monsoon regions reverse from winter to summer rather than every few days as in middle latitudes; the dominance of the Earth's vorticity over the local vorticity in middle latitudes; and the strong vertical coupling which characterizes systems of middle latitudes and contrasts with the near independence of the lower and upper troposphere in the tropics. In this book, Riehl describes all the important phenomena and places them in the context of the global general circulation. He seems to have read all that has been written on tropical meteorology and provides an excellent set of references. A notable feature is the inclusion of findings from recent expeditions to the tropics such as the Tropical Atlantic Experiment.

The problems of how energy is transported vertically in the tropics from its source, effectively at the sea surface, and how energy gets into the atmosphere from the warm ocean — both topics that Riehl has contributed to significantly — are dealt with extensively and there is ample material for students to carry the subjects further.

Tropical cyclones and the various ideas about their structure, mechanisms, formation and movement are covered in detail and occupy about one quarter of the book. There is a well-written chapter by Ferdinand Bauer on numerical prediction of hurricanes.

My only major complaint — from which Bauer's chapter is exempt — is that numerous typographical errors are scattered throughout the book; together with the awkward construction of some phrases and poor standardization of units, they often make the text hard to follow. A firm editorial hand needs to be applied before the next edition. Nevertheless, Riehl's book provides a unique source of information and deserves to be read by all meteorologists and to be the standard reference for many years. ☐

Reginald Newell is a Professor of Meteorology in the Department of Meteorology and Physical Oceanography at the Massachusetts Institute of Technology.

tRNA 2

J.P. Goddard

Transfer RNA: Biological Aspects. Edited by D. Söll, J.N. Abelson and P.R. Schimmel. Pp.578. (Cold Spring Harbor Laboratory: 1980.) $70, $84 outside USA.

THE publication of this book follows approximately six months after that of its companion volume *Transfer RNA: Structure, Properties and Recognition* (reviewed in *Nature* **284**, 287; 1980). The format of the two volumes is similar. Thus the contributors, who were participants at the Transfer RNA Meeting at Cold Spring Harbor in August 1978, have given us here a series of readable, authoritative and objective articles covering all the biological aspects of tRNA, except synthetase recognition, aminoacylation and ribosome interaction which were dealt with in the first volume. Division of the contributions into four sections — biosynthesis, gene arrangement, suppression and coding, and "other roles of tRNA" — is perhaps the best in the circumstances. However, the organization and expression of tRNA genes are so intimately linked that articles in the first two sections overlap and some of them also impinge upon suppression which has proved such a useful property in study of tRNA transcription and processing.

The opening section on tRNA biosynthesis begins, as do most sections in both volumes, with a useful general review of the topic by the session chairman at the meeting. There then follow a dozen shorter articles in which specific genetic and enzymological studies are thoroughly covered. Gene arrangement is introduced by a beautifully succinct review. The topics of the articles that follow, though broad-ranging, are somewhat unbalanced with four articles on *Drosophila*, including three on *in situ* hybridization, but none on tRNA genes in mitochondria or in *Xenopus*. No general reviews introduce the final two sections of the book. While a brief overview of the rather esoteric topic of suppression would have been most useful, the diverse topics of the final section could only be dealt with satisfactorily by individual articles. The volume concludes with three appendices on tRNA gene localization and codon usage.

One final comment should be made on the two-year delay in publication which, in some respects, is fortunate rather than regrettable. In mid-1978 there were tantalizing promises of rapid advance in some of the newer fields of study, such as tRNA gene organization in eukaryotes and removal of intervening sequences from tRNA precursors. The contributors have made an admirable job of updating their articles — of the 1300 references cited, nearly 200 date from 1978, 75 from 1979 and 16 from 1980. Thus most of the discoveries in the year following the 1978 meeting are reported in this volume.

The book has all the qualities one has come to expect from Cold Spring Harbor monographs and should find an appreciative readership among workers in tRNA research and in molecular biology generally. ☐

J.P. Goddard is a Lecturer in Biochemistry at the University of Glasgow.

Epithelial physiology: tribute to Jean Maetz

Clive Ellory

Epithelial Transport in the Lower Vertebrates. Edited by B. Lahlou. Pp.366. (Cambridge University Press: 1980.) £25, $55.

THIS book represents a memorial symposium held as a tribute to Jean Maetz by many of his friends, colleagues and collaborators. It was a meeting Jean would certainly have enjoyed, the emphasis being on fish and amphibian epithelial physiology, with many authors concentrating on endocrinological aspects. Aside from the obvious environmental attractions of working in Villefranche, Naples or Woods Hole, physiologists have become increasingly interested in fishes for studying the mechanisms of epithelial secretion. Fish gills and opercular skin, flounder intestine and shark rectal gland are all preparations which have generated valuable models and influenced thinking on epithelial function. These systems exercised Jean Maetz's considerable talents and represent the principal content of the present volume.

Papers on fish gills comprise half the total contributions. Thus, gill structure and function are covered well in the initial section, with emphasis on vasculature and functional morphology. The importance of the chloride cell in gill physiology is apparent from the number of times this topic recurs in the book, and from the descriptions of the exciting, isolated skin preparations from *Fundulus* and *Gillichthys*. New results, including data on gill permeability to large molecules, and some detailed electron microscopy produce tentative functional models for the chloride cell. Other gill transport systems beside Cl covered in the book include Na^+/NH_4^+ exchange and calcium transport. There are good biochemical presentations on gill Na, K-ATPase and the more controversial anion-stimulated ATPase. A salutary lesson is presented in the Na,K-ATPase chapter, where vanadate, a specific inhibitor of this enzyme *in vitro*, was found to be functioning on gills *in vivo* as a vasoconstrictor.

Kidney is mostly approached from an endocrinological point of view, although there are two impressive studies on single nephron physiology which emphasize the widely different roles for the kidney in marine and freshwater fish. Intestinal functions discussed include salt and amino acid transport, and amphibian skin is represented by three contributions mostly concerned with epithelial sodium transport. Endocrinological factors are emphasized in many of the contributions, but there are two small reviews dealing specifically with the hormonal control of ion transport.

Overall, there is much of interest in this book. Selection criteria for participants in such a memorial symposium obviously include factors which are not strictly scientific or rigorously thematic, which is reflected by some unevenness, with certain elements sitting less easily under the general title. There are also clear differences in scientific content, philosophy and merit among the various contributions, including some which are trivial or frankly eccentric. However, on balance this is a fitting tribute to Jean Maetz, which should prove valuable to fish physiologists and epithelial transport workers. ☐

Clive Ellory is a Lecturer in Physiology at the University of Cambridge.

Jean Maetz , a talented physiologist

Birds in brief

Robert Hudson

A Complete Checklist of the Birds of the World. By Richard Howard and Alick Moore. Pp.701. (Oxford University Press: 1980.) £17.50, $49.50.

THIS book comprises a straightforward listing of the living birds of the world, giving for each species the scientific and selected English name and a brief indication of geographical range; for polytypic species, named subspecies are also listed. Essentially, it is a condensed and partly updated version of the authoritative 15-volume *Checklist of the Birds of the World* edited by J.L. Peters and others (Harvard University Press, 1931–1979), but lacking the taxonomic and nomenclaturial comments, references and detailed distribution notes to be found in the larger work. The introduction to the present book suggests its major use will be as a handy personal checklist for the widely-travelled birdwatcher. Perhaps, but I will find it more useful as a quick reference for identifying unfamiliar bird names encountered in the serial literature, and in this respect its 59-page index is admirable.

Specialists in particular bird groups will not find it hard to quibble with points of detail, but on the whole the compilers offer a reasonable compromise between the often conflicting treatments to be found in avifaunal publications. Several other books of this type have appeared since 1974, the present one being the most comprehensive and therefore the most costly. It is the only one to include subspecies; but this is the weakest aspect of the book, since its authors are not taxonomists. A simplified listing of racial names gives a misleading impression of subspecific rigidity (whereas clinal situations are common even within land areas as small as the British Isles); moreover, named races present a continuum from well-differentiated semi-species to those hardly worthy of recognition, though this basic truth is not made evident to the reader. Thus, this is a potentially useful book, but not a definitive work. □

Robert Hudson is on the scientific staff of the British Trust for Ornithology, and is editor of the Trust's quarterly journal Bird Study.

Semiconductor lasers come of age

S. D. Smith

Physics of Semiconductor Laser Devices. By G. H. B. Thompson. Pp.549. (Wiley: 1980.) £22.75, $68.25.

THE semiconductor diode laser based upon the radiative recombination of carriers injected across a p–n junction is now nearly 20 years old from the date of the original concept. It has developed from a laboratory speciality operating only at cryogenic temperatures into a range of optoelectronic devices of application in optical fibre communication, military systems, printing, infrared spectroscopy, pollution detection and short-pulse work, to mention only part of the list.

This excellent and comprehensive book opens with a most readable chapter outlining the history, concepts and basic principles, without the use of mathematics, emphasizing the dramatic effect of the introduction of hetero-structures, using layers of alloy material, which separately confine the injected carriers and guide the generated optical waves with favourable effects on threshold current and temperature of operation. In the next 100 pages the author discusses the basic processes of light emission and laser action, and includes appropriate development of absorption, stimulated and spontaneous processes, band structure in the presence of heavy doping, and recombination times. Gain–current relationships, threshold currents and efficiencies are calculated and compared with experimental results for the basic or homostructure p–n junction laser with a simple resonator, for which the mode properties are also given. The treatment owes something to the earlier *Semiconductor Lasers and Light Emitting Diodes* by Kressel and Butler (Academic, 1977), but is more continuous and complete at the expense of rather intricate notation. I found this section a useful text for part of a graduate course on optoelectronic devices held at the Optical Sciences Center of the University of Arizona.

Later chapters deal with heterostructure lasers, optical waveguides and all the many variations of laser geometries in considerable detail. Methods of fabrication and the physics of dynamical response are also considered.

The only notable omission is the absence of discussion in any detail of the lead salt family of diode lasers and their application in high resolution infrared spectroscopy, perhaps not surprising since the book concentrates on the GaAs alloys. However, the basic physical principles for all types of semiconductor diode lasers are well covered which is a stated aim of the book. The author does not claim to be comprehensive in citing the literature — a difficult task in this active field — but nevertheless provides copious references in each chapter.

The book frequently examines the relation between semiconductor lasers and other types of lasers — emphasizing the high gain values, for example. It is thus easy to see what semiconductor injection lasers have not achieved — visible room temperature operation, high powers or wide-band tuning in one device.

With the slight qualification that the book's title is not quite consistent with its concentration on the GaAs injection diode laser family, it is to be generally recommended for a variety of uses in research, application and teaching. □

S. D. Smith is Visiting Professor at the Optical Sciences Center, University of Arizona, Tucson, and Head of the Physics Department at Heriot-Watt University, Edinburgh.

Organic infrared–structure correlations

P.C. Crofts

Infrared Characteristic Group Frequencies. By G. Socrates. Pp.153. (Wiley: 1980.) £24, $72.

INFRARED spectroscopy is perhaps the most generally applicable and widely used physical method for investigating structures of organic compounds. Although qualitatively rationalized by classical physical theory, it is an essentially empirical activity in which absorption bands reveal individual chemical bonds or larger submolecular units whose vibrations interact with radiation of the observed frequencies. Users of the technique thus require comprehensive collections of assignments of recorded absorption frequencies to particular functional groups or other structures. Although described in the preface as "a simple introduction to characteristic group frequencies", this book is a substantial and valuable work, simple only in its arrangement and empiricism and not in any restriction of its subject matter.

An introductory chapter contains three successively more detailed charts of the range 4000–200 cm^{-1}; the first shows regions without absorptions and infers absences of particular groups, the second relates observed bands to possible vibrations, and the third shows absorption regions for many specified compound types. This is followed by 19 chapters dealing with individual substituents of particular importance (e.g. O–H, C = O), with collections of related substituents (e.g. triple-bonded groups, halogen compounds), or with larger structural features (e.g. alkane residues, six-membered heterocycles). A short section surveys X–H stretching overtones in the 14000–4000 cm^{-1} region. Each chapter contains extensive tables of absorption bands, in wavenumber and wavelength units, with well-written explanatory text and many references.

A compilation of this type can be only a starting point in an infrared investigation — which also requires comparison with reference spectra of model compounds — but when used intelligently this book should point many investigators towards solution of their problems. It is well printed, with wide, short, double-column pages which are convenient when examining a spectrum, and is recommended to all who use infrared spectroscopy in structural investigations.

P.C. Crofts is a Senior Lecturer in Chemistry at the University of Manchester Institute of Science and Technology.

CORRESPONDENCE

Continued from page 742

anomalies in the data very successfully. For instance, he showed that in the Cornish sample the biggest single annual decline in the incidence of herd breakdowns was from 5.5 to 3.2 per cent in 1975–76 (a 42 per cent decline). Yet by 31 August 1976 only ten "fire-brigade" cases had been completed in Cornwall[1], an area of approximately 355,000 hectares (a fire-brigade action normally involves the removal of a small number of badger social groups around a farm with a herd breakdown). Is Dr Yates telling us that this 42 per cent decline in Cornwall was the instant result of ten completed fire-brigade actions? If ten fire-brigade actions could be so successful, it is surprising that the TB problem was not solved long ago. In other areas a similar situation can be seen, with significant reductions in the number of herd breakdowns before the onset of badger gassing, or before effective measures could have been achieved by the badger gassing programme. The data are not conclusive, but there is good evidence to suggest that the incidence of TB was undergoing a decline before the onset of gassing, and that to attribute the decline solely to the gassing campaign is not justified.

Dr Yates also contested that only 15 per cent of the Cornish herd breakdowns could be attributed to badgers, and "presumed" that badgers were responsible in many more cases. Lord Zuckerman (*Nature* 19 February 1981, p.628) also contested this point, saying that badgers in Cornwall have only been routinely investigated as a possible source of infection since 1974. However, his figures still demonstrate our original point; even since 1974 badgers were still only believed responsible for a minority of breakdowns, and even these figures are very dubious. In his letter Lord Zuckerman states that the majority of herd breakdowns in Cornwall supposed to have originated from badgers were attributed to infected badgers living up to two miles from the breakdown, and 28 per cent were attributed to infected badgers found more than two miles away. But in areas of relatively high badger density, such as Cornwall, badger territories are small, about 75 hectares (report, p.37). Ministry of Agriculture, Fisheries and Food (MAFF) studies in Gloucestershire[2] showed that in an area of high badger density, itinerant badgers were rare, and long distance movements outside the group territory were not recorded. The available information suggests that in Cornwall badgers are very unlikely to make contact with a cattle herd two miles away. Lord Zuckerman might as well tell us that in 100 per cent of cases an infected badger was found within twenty miles; such a figure is no less meaningful than those presented by Lord Zuckerman.

Figures such as those discussed are of little value if we do not understand how and where transmission takes place. As we said in our original letter, the mere presence of infected badgers does not always result in herd breakdowns. In his letter, Lord Zuckerman states that transmission of TB from badgers to cattle occurs in pasture that has been contaminated with sputum, pus, urine and faeces. It has never been proven that this is the sole point of transmission, nor even the major point of transmission, and this is another area in which further research is needed. As long ago as 1974, MAFF staff[3] pointed out that "On many occasions badgers have actually been observed in cattle buildings, presumably in search of food, and contamination of cattle food concentrates may also be important [in transmission]" and "On a number of occasions farmers have reported finding badgers in farm buildings eating cattle feeding stuffs". In his report, Lord Zuckerman (p.35) said that badly diseased badgers may leave their sett and take up refuge in farm buildings. How common is such behaviour? Further investigation might show that farm buildings are a major point of transmission, and if so a significant reduction in herd breakdowns might be achieved by a simple improvement in animal husbandry. Actions such as these to complement the gassing programme do not seem to have been considered by Lord Zuckerman; we feel that they should be.

Lord Zuckerman asserts that during the period of the moratorium (October 1979 to October 1980) the increase in the percentage of reactor herds in the affected counties of the South West was a direct result of halting badger control measures. This assumption was supported by Dr Yates in his letter, where he showed that the incidence of TB in badgers increased *immediately* following the moratorium on gassing. This not only totally ignores the likelihood of natural cyclic trends in TB prevalence, as discussed in our original letter and the reply by Dr Yates, but also requires us to believe that following the moratorium there was an immediate increase in the badger population, and consequently of the numbers of badgers infected with TB. It must be remembered that although no new areas were gassed during the moratorium, gassing was continued "to maintain freedom from the disease in areas already cleared of it"[2]. Since the moratorium only applied to areas not previously gassed, it seems reasonable to presume that, in the absence of any evidence to the contrary, the badger population was fairly stable in those areas. Badgers are long-lived animals with a relatively slow reproductive rate. Since the moratorium only lasted one breeding season, even if there was a population increase it could only have been small. And even presuming that there was an upward trend in badger population density during the period of the moratorium, there is no unequivocal evidence that TB in badgers is density dependent. Lord Zuckerman's report (p.68, 70) shows that TB is not only prevalent in badgers in areas of high density, but also in areas such as South Dartmoor, where the badger population is very low. Also, when considering Lord Zuckerman's and Dr Yates' arguments, it is necessary to take account of the rate of development of the disease in badgers. Experiments by MAFF scientists suggest that this may take several months[1]. In affected areas of the South West, tuberculin testing of cattle is carried out annually[3], and so there will be a further delay between possible infection of cattle and their subsequent discovery at tuberculin testing. Clearly there is no evidence to support Lord Zuckerman's and Dr Yates' argument that TB in badgers and cattle immediately increased as a result of the moratorium on gassing, and it is not surprising that an increase in TB in badgers was not seen in all areas, the point we made in our original letter.

Much of Lord Zuckerman's latest letter deals not with the TB problem, but is an attack on the Mammal Society and some of its members. Lord Zuckerman questions the right of the society to discuss the subject, since he suggests that the society is not fully competent in all the relevant fields of expertise. While this is a debatable point, no one has ever questioned Lord Zuckerman's right to express his opinion.

Also, Lord Zuckerman is unfamiliar with the aims or constitution of the Mammal Society, and so it is necessary to correct some more misleading statements. We are not a conservation society, and such interests are outside our remit. However, at our AGM on 14 April 1973, a motion from the membership mandated the Council:- (1) "to encourage the discussion of contentious issues [relating to the study of mammals] with the aim of showing where more information is needed in order to reduce the uncertainties of the issue", and (2) "to write, when appropriate, general letters asking for action or expressing concern". These are quotations from the minutes of that meeting, and clearly we have acted in accordance with the wishes of our membership. Lord Zuckerman's lengthy discussion on whether other societies can act in a similar manner is totally irrelevant. And of course our statements are not anonymous; they have been made by the officers of the Mammal Society, and a full list of elected officers is published.

The Mammal Society hopes that the badger/TB problem can be solved soon, and that some means can be found whereby the incidence of TB in cattle in the South West can be permanently reduced. We still feel that this aim can only be achieved by a critical analysis of all the data. We feel that the Zuckerman report does not help solve this complex problem; the only statistical treatment presented in the report is the calculation of percentage changes. This is clearly unacceptable for a complex epidemiological problem. Since the data are not conclusive, and since none of our original points have been answered satisfactorily, we suggest that the Minister of Agriculture should establish a Scientific Advisory Group, containing a small number of independent scientists such as wildlife epidemiologists and statisticians, who can analyse the data in detail and advise the Consultative Panel on Badgers and Tuberculosis, which currently lacks such expertise.

Science-Teaching in Schools. By the Rev. W. Tuckwell
The late Professor Graham. By Prof. Williamson, F.R.S.
Meeting of the German Naturalists and Physicians at Innsbruck. By A. Geikie, F.R.S.

Payment may be made in any currency at the prevailing exchange rate. Cheques should be made payable to **Nature.** Prices include postage and packing.

To order please complete the coupon below, or write, enclosing the correct remittance.

Circle No. 56 on Reader Enquiry Card.

SHORR, J. E., SOBEL, G. E., ROBIN, P. and CONNELLA, J. A. (eds). Imagery; Its Many Dimensions and Applications. Proceedings of the First Annua Conference of the American Association for the Study of Mental Imagery, held at Los Angeles, June 1979. Pp.398. ISBN 0-306-4056-7. (Plenum: 1980.) $32.50.

SKUTCH, A. F. A. Naturalist on a Tropical Farm. Pp.397. ISBN 0-520-03802-9. (University of California Press: 1980.) £10.25.

SMIL, V. and KNOWLAND, W. E. (eds). Energy in the Developing World. The real energy crisis. Pp.386. Hbk ISBN 0-19-854425-1; pbk ISBN 0-19-854421-9. (Oxford University Press: 1980.) Hbk £25; pbk £12.50.

STIBIC, V. Personal Documentation for Professionals. Means and Methods. Pp.214. ISBN 0-444-85480-0. (North-Holland: 1980.) $29.25, Dfl. 60.

WHEELWRIGHT, H. W. Bush Wanderings of a Naturalist. Pp.272. ISBN 0-19-54226-6. (Oxford Unversity Press: 1980.) £8.95.

WOOD, C. (ed.). Human Health and Environmental Toxicants. Royal Society of Medicine International Congress and Symposium Series No. 17. Pp.210. Flexi ISBN 0-12-794919-4. (Academic: 1980.) £15, $36.

YALLOP, H. J. Explosion Investigation. Pp.276. ISBN 0-7073-0272-2. (Scottish Academic Press: 1980.) £20.

Mathematics

ANTOINE, J.-P. and TIRAPEGUI, E. (eds). Functional Integration Theory and Applications. Proceedings of the Colloquium held in Louvain-la-Neuve, Belgium, November 1979. Pp.355. ISBN 0-306-40573-3. (Plenum: 1980.) $42.50.

CLEMENS, C.H. A Scrapbook of Complex Curve Theory. Pp.186. ISBN 0-306-40536-9. (Plenum: 1980.) $22.50.

FRAUENTHAL, J.C. Mathematical Modeling in Epidemiology. Pp.118. Flexi ISBN 3-540-10328-7. (Springer-Verlag: 1980.) DM 36, $21.30.

MISCHENKO, E.F. and ROZOV, N.K. Differential Equations with Small Parameters and Relaxation Oscillations. Mathematical Concepts and Methods in Science and Engineering, Vol.13. Pp.228. ISBN 0-306-39253-4. (Plenum: 1980.) $29.50.

PLUMPTON, C. and MacILWAINE, P.S.W. New Tertiary Mathematics. Vol.1, Part 1, Pure Mathematics: The Core. Pp.401. Hbk ISBN 0-08-025031-9. (Pergamon: 1980.) Hbk £17.40; $40, flexi £6.90, $15.95.

PLUMPTON, C. and MacILWAINE, P.S.W. New Tertiary Mathematics. Vol.1, Part 2, Basic Applied Mathematics. Pp.229. Hbk ISBN 0-08-025035-1; flexi ISBN 0-08-021645-5. (Pergamon: 1980.) Hbk £17.40, $40; flexi £6.90, $15.95.

PLUMPTON, C. and MacILWAINE, P.S.W. New Tertiary Mathematics. Vol.2, Part 1, Further Pure Mathematics. Pp.803. Hbk ISBN 0-08-025033-5; flexi ISBN 0-08-021644-7. (Pergamon: 1980.) Hbk £17.40, $40; flexi £6.90, $15.95.

MARCHUK, G.I. and NISEVICH, N.I. (eds). Mathematical Methods in Clinica Practice. Pp.116. ISBN 0-08-025493-4. (Pergamon: 1980.) £25, $60.

TEVES, F. Introduction to Pseudodifferential and Fourier Integral Operator Vol.1, Pseudodifferential Operators. Pp.299. ISBN 0-306-40403-6. (Plenum: 1980.) Np.

WOODHOUSE, N. Geometric Quantization. Pp.316. ISBN 0-19-853528-7. (Clarendon Press/Oxford University Press: 1981.) £27.50.

Astronomy

HEIDMANN, J. Relativistic Cosmology. An Introduction. Pp.168. Flexi ISBN 3-540-10138-1. (Springer-Verlag: 1980.) DM 48, $28.30.

WAYMAN, P.A. (ed.). Proceedings of the 17th General Assembly, Montreal 1979. Transactions of the International Astronomical Union, Vol.XVIIB. Pp.526. ISBN 90-277-1159-3. (Reidel: 1980.) Dfl.130, $68.50.

Physics

BALLHAUSEN, C.J. and GRAY, H.B. Molecular Electronic Structures: An Introduction. Pp.133. ISBN 0-8053-0452-5. (Benjamin/Cummings, California: 1980.) $14.50.

BALTES, H.P. (ed.). Inverse Scattering Problems in Optics. Topics in Current Physics, Vol.20. Pp.313. ISBN 3-540-10104-7. (Springer-Verlag: 1980.) DM 78, $46.10.

BECK, R., ENGLISH, W. and GÜRS, K. Table of Laser Lines in Gases and Vapors. 3rd Edn. Springer Series in Optical Sciences, Vol.3. Pp.247. ISBN 3-540-10347-3. (Springer-Verlag: 1980.) DM 62, $36.50.

BELLAMY, L.J. The Infrared Spectra of Complex Molecules. Vol.2, Advance in Infrared Group Frequencies. 2nd Edn. Pp.299. ISBN 0-412-22350-3. (Chapman & Hall: 1980.) £15.

BOLTON, W. Fields. Study Topics in Physics, Book 5. Pp.95. Flexi ISB 0-408-10656-5. (Butterworths: 1980.) £1.60.

BOLTON, W. Rays, Waves and Oscillations. Study Topics in Physics, Boo Pp.95. Flexi ISBN 0-408-10657-3.

BRUCE, A.D. and COWLEY, R.A. Structural Phase Transitions. Pp.326. IS 0-85066-206-0. (Taylor & Francis, London: 1981.) £15.

CANNATA, F. and ÜBERALL, H. Giant Resonance Phenomena Intermediate-Energy Nuclear Reactions. Springer Tracts in Modern Physic Vol.89. Pp.112. ISBN 3-540-10105-5. (Springer-Verlag: 1980.) DM 52, $30.60.

CUNNINGHAM, R.E. and WILLIAMS, R.J.J. Diffusion in Gases and Poro Media. Pp.275. ISBN 0-306-40537-7. (Plenum: 1980.) Np.

DEGIORGIO, V., CORTI, M. and GIGLIO, M. (eds). Light Scattering Liquids and Macromolecular Solutions. Proceedings of the Workshop, Cen Informazioni Studi Esperienze, Segrate, Milan, May 1979. Pp.295. IS 0-306-40558-X. (Plenum: 1980.) $35.
